An Advertising Policy

The Board of Regents of the American College of Physicians, official publishers of "Annals of Internal Medicine," has initiated a definite policy for the acceptance only of advertisements of products relevant to the practice of Internal Medicine, or one of the affiliated specialties. Publishers of high-grade medical books and manufacturers of the most reputable instruments and therapeutic products will find this journal an advertising medium for reaching the preferred class of internists. The volume of advertising in any one issue will be limited, no advertisement of less than one-quarter page will be accepted, no advertisement will be lost in a mass of other advertising.

Advertising in this journal is not a duplication of advertising in general medical journals, for it is maintained that specialists will read specialized advertising in a journal devoted to their particular field, whereas they scarcely more than scan general advertising.

Members and subscribers are urged to give special attention to these advertisements, and, other considerations being equal, to give PREFERENCE to the advertisers using these columns.

ORTHODIASCOPY

An Analysis of Over
Seventeen Hundred
Orthodiascopic Examinations

Outstanding features

A
MACMILLAN
MEDICAL
MONOGRAPH

Ready in
August

Probably
\$3 50

- Unusual efficiency not only in determining heart size and detecting early stages of cardiac enlargement but also in revealing certain easily distinguishable changes in the shape of the cardiovascular shadow characteristic of various types of heart disease
- Enables the examiner to detect an early lesion of the mitral valve, and as a corollary, to differentiate between a functional and organic apical systolic murmur
- Describes the apparatus used and the details of the procedure
- Orthodiascopy is as valuable in treatment as in diagnosis
- Nomograms determine without calculations the predicted frontal area and transverse diameter
- Includes correlation between the common physical signs and the orthodiascopic findings lending new significance to ordinary procedures

IMPORTANT NEW PUBLICATIONS

NEW (6th) EDITION

JUST READY

THE TREATMENT OF DIABETES MELLITUS

By ELLIOTT P. JOSLIN, M.D. (Harvard), M.A. (Yale)

Medical Director, George I. Baker Clinic, New England Deaconess Hospital, Clinical Professor of Medicine, Harvard Medical School, etc.

With the Cooperation of HOWARD F. ROOT, M.D., PRISCILLA WHITE, M.D.,
ALEXANDER MARBLE, M.D.

Octavo 707 pages illustrated Cloth \$7.00 net

THE discovery of protamine insulin marks the beginning of a better era for the diabetic. It has necessitated a complete revision of this standard work and the addition of two new chapters. The book now indicates how the transfer of the patient from regular insulin to protamine insulin may be effected and how the hazards involved in the process may be avoided. The author and his associates have here recorded their experience with more than twelve hundred cases in which protamine insulin has been used. The results checked and rechecked have convinced them that protamine insulin offers unsuspected possibilities for treating diabetic patients. Other new factors in the treatment of diabetes are here summarized. No previous edition of this work has been so thoroughly up to date. The work presents a combination of scientific and clinical experience which is unequalled.

NEW WORK

JUST READY

PEDIATRIC DIETETICS

By N. THOMAS SAXL, M.D., F.A.C.P., F.A.A.P.

Associate and Lecturer in Diseases of Children, New York Post Graduate Medical School, Columbia University, Assistant Attending Physician, Babies Ward, New York Post Graduate Hospital, Director of Pediatric Clinics, Church of All Nations, New York, Fellow of New York Academy of Medicine, American Society for the Advancement of Science, etc.

Octavo 565 pages illustrated with 57 engravings and 2 colored plates Cloth \$7.00 net

THIS book is unique in that it correlates and collects in a single volume all the available data on diet therapy for the sick child. It is a work that will be as useful to general practitioners as to pediatricians. It offers nothing that the author himself has not tested and found to be of practical value, physiologically sound and scientifically accurate. After considering mechanics and chemistry of digestion during infancy and childhood, the book discusses the various forms and types of foods, their distribution, qualitative and quantitative compositions and their application in modern pediatric dietetics, as well as the role in metabolism of vitamins and minerals. There is a special section on infant feeding, both maternal and artificial, the latter incorporating for the first time in one volume a complete summary and analysis of the best known proprietary pediatric foods.

TRAUMA AND DISEASE

Edited by LEOPOLD BRAHDY, B.S., M.D.

Physician in Charge of Industrial Diseases and Accidents in the
Office of the Corporation Counsel of the City of
New York, New York City

and SAMUEL KAHN, B.S., M.D.

Medical Examiner in the Bureau of Workmen's Compensation
of the Department of Labor, State of New York
New York City

Octavo 613 pages illustrated Cloth \$7.50 net

THIS book has been written to provide wider and more accurate knowledge of the etiological relationship between trauma and disease. The rise of accident rates, the compensation laws and the growth of industrial medicine have all stimulated the demand for such information. This work is a symposium to which twenty-four recognized authorities have contributed their knowledge of the relations between trauma and the diseases with which they are most familiar. The work develops the underlying principles on which, in any given case, medical opinion may be safely based. It shows the effect of a single trauma—either physical or psychic—in producing disease and in influencing its course. It supplies the physician confronted with the problem of etiology with definite facts based on pathological, clinical and laboratory investigation. The editors believe that it is on such data that he should rely rather than on the information derived from previous court decisions. For these reasons they have selected as contributors eminent teachers and specialists in individual fields of medicine rather than physicians specializing in so-called medico-legal practice.

The "HINDLE" *always modern*

Developments in the Hindle Electrocardiograph are not announced in headlines but are, nevertheless, continuous. Starting with a basically sound instrument in 1914, changes have been so gradual that the Medical Profession was hardly conscious of the progress being made. Every succeeding instrument incorporated all the new features but only after the soundness of each new feature had been proved in practice.

The new Hindle "All-Electric" models are available in stationary, mobile and portable types for hospitals, clinics and private offices.

Cambridge does not ask the Cardiologist to wait for *something* in course of development but not proved in the field. Whenever a doctor purchases a Hindle, he can feel certain he is getting an instrument incorporating over twenty years of development—an instrument of proved accuracy and dependable performance.

ELECTROCARDIOGRAPH

A Contribution to the Treatment of **DROPSY**

In the New England Journal of Medicine for February 27, 1936, Dr Henry A Christian makes the following statement

Very recently a definite advance has been made in that a mercurial diuretic has been prepared by Campbell Products, Inc. which is very satisfactorily effective when given by rectum in the form of a suppository. This obviates the necessity of intravenous or intramuscular dosage for mercurial diuretics but still requires the preliminary days on ammonium chloride. Experience shows that this treatment may be kept up for months with no bad effects."

Well known cardiologists recommend Mercurin in the treatment of edema of congestive heart failure and nephrosis, because it fulfills the requirements of an efficient and dependable mercurial diuretic which has the important advantage of simple rectal administration.

SUPPLIED in boxes of 5 and 25 suppositories (0.5 Gm.)

MERCURIN SUPPOSITORIES

β -methoxy γ hydroxymercuri propylamide of camphoric acid-sodium salt (with 20% of the free acid)

For oral administration in the treatment of
Hemolytic Streptococcal Infections—

SULFANILAMIDE

(Para aminobenzenesulfonamide)

The Therapeutic Indications include—acute puerperal sepsis, erysipelas, tonsillitis, and complications attributable to hemolytic streptococci in scarlet fever, rheumatic fever, measles

Clinical reports indicate that this drug may be of value in other types of infection, particularly in meningococcal infections

The drug is rapidly excreted—partially in acetylated form in the urine—and a daily maintenance dose is indicated for several days

Suggested dosage is not less than 5 grains (0.325 grams) for each 20 lbs body weight during the first 24 hours of treatment Repeat a second day if necessary—subsequently about half this amount for maintenance of an effective concentration in the blood

The term "SULFANILAMIDE" has lately been suggested by the Council on Pharmacy and Chemistry of the American Medical Association as a more convenient designation for para-aminobenzenesulfonamide

PACKAGES Bottles of 25 and 100 Tablets
5 grains (0.325 grams) each

EDUCATION

Education is more than classroom exercise. In a broad sense, it is the development of all those natural faculties which dominate physical and mental character. Where physical education has been neglected as in the instance of constipation, wise counsel and selected treatment often expedite the return to normal function. As an adjunct to the treatment of diet and exercise, Petrolagar is

a useful and convenient method of correcting constipation. By its bland lubricating action, Petrolagar produces soft well formed stools which are easy to evacuate. Petrolagar is prepared in five types — Plain, with Phenolphthalein, with Milk of Magnesia, Unsweetened and with Cascara — to provide a range of treatment adaptable to the individual patient. Petrolagar Laboratories, Inc., Chicago, Ill.

Petrolagar is a mechanical emulsion of pure liquid petrolatum (65% by volume) and agar agar. Accepted by the Council on Pharmacy and Chemistry of the American Medical Association for the treatment of constipation.

Petrolagar

Ephedrine Products Lilly

● Topical application of Ephedrine to mucous membranes represents but a single example of the therapeutic value of this drug.

Indications for Ephedrine include asthma, rhinitis, sinusitis, and the manifestations of allergy, such as hay fever and urticaria

Ephedrine in moderate doses is stimulating to the heart and circulatory system. Important advantages of Ephedrine are its relatively prolonged action and effectiveness by oral as well as parenteral administration.

Among the prescription forms of Ephedrine which are available are Ephedrine Inhalants, Lilly, Pulvules (filled capsules), Ampoules, and Hypodermic Tablets.

**HOW ABOUT ITS
ACCURACY?**

WE are glad you raised the question of accuracy, Doctor, in connection with the new G-E Electrocardiograph. It is a point which *merits emphasis*.

In most fine modern instruments—including our electrocardiograph—years of experience in building, tireless effort, and exhaustive research are reflected in improved design. Just look about you. That telephone you are using is certainly better, even if smaller, than its bulky predecessors, that watch on your wrist is no less accurate because of its more convenient size and shape.

The new G-E Electrocardiograph, while retaining the time-tested basic principle of the universally respected older model, is more readily portable, simpler to operate—yes, and considerably lower in price. From every standpoint it is *a better instrument*. It places consistently accurate electrocardiography within the reach of the average practitioner, gives him a really dependable apparatus for which he will have daily need, offers an in-

vestment in diagnostic equipment which will prove to be sound.

The whys and wherefores of the superiority of this electrocardiograph over its contemporaries are told in an easy to read, interesting booklet. Send for your copy, and at the same time make the initial move toward a private demonstration of the G-E Electrocardiograph. Mail the handy coupon—today.

—NO OBLIGATION INCURRED—

C 47

Send me your booklet 7P 215 which describes the new G-E Electrocardiograph, and have your local representative arrange with me for an early showing of the instrument in my office.

For bland diet therapy, especially ULCER cases — PABLUM

FAR too often the bland diet prescribed for gastric ulcer, colitis, and similar gastro-intestinal disorders is a deficient diet. An analysis made by Troutt of ulcer diets used by 6 leading hospitals in different sections of the country showed them to be "well below the Sherman standard of 15 milligrams" in iron and low in the water-soluble vitamins¹ "Vitamin B would appear to be represented at a maintenance level in most cases," writes Troutt, "but the possible relation of vitamin B to gastro-intestinal function and appetite should make one pause before accepting a low standard."

Low in Fiber — High in Iron

Pablum is the only food rich in a wide variety of the accessory food factors that can be fed over long periods of time without danger of gastro-intestinal irritation. Its fiber content is only 0.9%. Yet Pablum contains 37 times more iron than farina and is an excellent source (+ + +) of vitamins B and G, in which farina is deficient. Supplying 8½ mgms. iron per ounce, Pablum is 8 times richer than spinach in iron.

Rich in Vitamin B

The high vitamin B content of Pablum assumes new importance in light of recent laboratory studies showing that avitaminosis B predisposes to certain gastro-intestinal disorders. Apropos of this, Cowgill says, "Gastric ulcer is another disorder which can conceivably be related to vitamin B deficiency. Insofar as the treatment of this condition usually involves a marked restriction of diet the occurrence of at least a moderate shortage of this vitamin is by no means unlikely. Obviously the length of the period of dietary restriction is an important determining factor. Dalldorf and Kellogg (1931) observed in rats subsisting on carefully controlled diets that the incidence of gastric ulcer was greatly increased in vitamin B deficiency. Observations of this type merit serious consideration."²

Although Pablum has a low fiber content it is 37 times richer than farina in iron and in calcium, 4 times richer in phosphorus and 4½ times richer in copper.

Requiring no further cooking, Pablum is especially valuable during the healing stage of ulcer when the patient is back at work but still requires frequent meals. Pablum can be prepared quickly and conveniently at the office or shop simply by adding milk or cream and salt and sugar to taste. Pablum has the added advantage that it can be prepared in many varied ways—in muffins, mush, puddings, junket, etc. Further, Pablum is so thoroughly cooked that its cereal-starch has been shown to be more quickly digested than that of farina, oatmeal, cornmeal, or whole wheat cooked four hours in a double boiler (studies *in vitro* by Ross and Burrill).

In addition to all the above points Pablum has the advantage of being the only base-forming cereal (except Mead's Cereal which is the uncooked form of Pablum).

Pablum consists of wheatmeal, oatmeal, cornmeal, wheat embryo, alfalfa, yeast, beef bone, iron salt and sodium chloride.

RECENT KNOWLEDGE CONCERNING INFLUENZA

By RICHARD E. SHOPL, M.D., *Princeton, New Jersey*

FROM the time of Pfeiffer's announcement of its discovery in 1892¹ to 1918 *H influenzae* was quite generally regarded as the agent responsible for epidemic influenza. Because of this general belief, much of the huge volume of work done during the 1918-1920 pandemic was concerned with a further study of the relationship of this bacterium to the disease. The results obtained were confused and contradictory, some seemed to support the view that *H influenzae* was the cause of the pandemic disease, others opposed it. An unbiased review of the large literature on the subject leads to the conclusion that, while the question had still to be considered controversial, the claims for *H influenzae* as the causative agent of influenza were less convincing after the 1918 pandemic studies than they had been before.

Some of the opponents of the Pfeiffer bacillus theory suspected that the primary etiological agent of influenza might be a filtrable virus. Evidence for the virus theory obtained during the 1918-1920 pandemic was, however, extremely sketchy and unconvincing. A few investigators, notably Selter² and Leschke³ seem to have reproduced the disease in a small number of human subjects by spraying them with filtered respiratory tract secretions and washings from influenza patients. But against these apparently positive results must be placed the negative findings of other workers in much larger series of attempted infections. Kruse,⁴ Friedberger and Konitzer,⁵ Lister and Taylor,⁶ and McCoy, Rosenau et al.⁷ entirely failed to produce illness by spraying human subjects with filtered respiratory tract secretions from influenza patients. While it must be admitted that man is a bad experimental animal at best and practically useless when employed for experiment during an epidemic, it is apparent that, so far as published work is concerned, the evidence against a filtrable virus as the cause of influenza was more con-

* John Phillips Memorial Medal address presented at the St. Louis meeting of the American College of Physicians, April 21, 1937.

From the Department of Animal and Plant Pathology of The Rockefeller Institute for Medical Research, at Princeton, N. J.

vincing than that in favor of it. The conclusion seems warranted that, so far as experimental work done during the 1918-1920 pandemic is applicable, the theory that held influenza to be caused by a filterable virus was at least as highly controversial as the one which maintained the disease was caused by Pfeiffer's bacillus.

This much of a review of the older work on influenza has been necessary in order to prepare the way for an account of recently acquired knowledge concerning the disease. It is apparent to all, I believe, that one of the most serious handicaps under which earlier investigators worked was the lack of an experimental animal, other than man, susceptible to influenza. It is equally clear now that the recent increase in our knowledge of influenza has resulted largely from the discovery that certain of the experimental animals can be employed in studying the disease.

SWINE INFLUENZA

The statement that no animal except man acquires influenza under natural conditions is encountered frequently in the older medical literature. However, in the late summer or early autumn of 1918 a new disease which appeared among swine in the Middle West seemed to challenge this old contention. The new disease was not a sporadic and localized outbreak, actually millions of swine became ill and thousands died during the first few months of its prevalence. By October and November it was widespread among swine herds in Iowa and other parts of the Middle West. Dr. J. S. Koen, who first recognized the disease as being different from any previously encountered in swine, was so much impressed by the coincidental prevalence of human influenza and by the resemblance of the illness seen in man to that occurring at the time in hogs that he became convinced that the two were actually the same.⁸ He therefore gave the name "flu" to this new swine disease. The opinion of Koen that "flu" represented an entirely new swine epizootic disease, and that swine might have been infected in the first instance from man, was shared by some veterinarians and many farmers in the Middle West.⁹ Furthermore "flu" proved a generally accepted popular designation for the condition, though in the scientific literature it is usually referred to as "swine influenza." The disease has recurred each autumn, since its first appearance, in epizootics which vary from year to year in their severity and extent.

Now allowing for certain differences between swine and man, swine and pandemic human influenza were indeed very much alike. In addition to their coincidental prevalence in the autumn of 1918, the clinical and pathological pictures of the two diseases were similar. In both, fever, anorexia, cough and other signs referable to the respiratory tract were prominent, a leukopenia occurred in both diseases, and in both the degree of prostration was out of all proportion to the rest of the clinical picture. In both diseases the onset was sudden, the course short, and convalescence slow but usually uneventful. Both conditions appeared to be highly con-

tagious Death, when it occurred in either the human or swine disease, was frequently the result of a "water-logged," bloody, edematous pneumonia. It is, of course evident that all of these similarities could have been a matter of chance and that one is not warranted in drawing conclusions as to the relationship of the two diseases merely on the basis of clinical and pathological resemblances. Their etiological agents should be known and compared. In the beginning, or at the time that swine influenza gained prominence as a veterinary problem, a comparison of this nature was impossible because the causative agent of neither disease was known.

The etiology of swine influenza was finally determined in 1931 and it proved to be different in character from that of any hitherto known disease of animals or man. Instead of being caused by a single agent, swine influenza was found to result from infection with two such agents, one a virus, the other a bacterium, acting synergistically¹⁰. The virus differed from any previously known, and caused, when administered alone to swine, an extremely mild, indefinite, usually afebrile ailment, which, for want of a better name, was designated "filtrate disease". The bacterium was very similar to, if not identical with, the non-indol producing type of Pfeiffer's *H influenzae* and was named *H influenzae suis*¹¹. When administered alone to swine it proved non-pathogenic.

Here then in swine influenza was a bacterium like that believed by many to be responsible for influenza in man. Leaving out of consideration for the moment the possibility that *H influenzae suis* and *H influenzae* might play analogous rôles in their respective diseases, it was striking to find these similar bacteria closely associated with like diseases occurring in two animal species. The finding furnished additional evidence of a possible relationship between swine and human influenza. Furthermore, the demonstration that swine influenza was caused by the combined activity of this Pfeiffer bacillus-like organism and a filtrable virus made the suggestion obvious that the swine disease might actually be an etiological replica of human influenza. The thing lacking so far as the human disease was concerned, and this was quite important, was positive proof that a filtrable virus was present. Though long suspected, none had been conclusively or convincingly demonstrated. But there was not long to wait.

A FILTRABLE VIRUS IN HUMAN INFLUENZA

In 1933 Smith, Andrewes, and Laidlaw¹² transmitted a disease to ferrets by inoculating intranasally filtrates of pharyngeal washings from cases of epidemic influenza in man. The ferret disease proved to be serially transmissible, and was characterized by a two-day incubation period, a diphasic temperature response, symptoms of nasal catarrh, and variable systemic disturbances. The mucous membranes of the nasal passages of ferrets killed during the first or second febrile periods were acutely inflamed. In their original work, Smith, Andrewes and Laidlaw recovered the virus from the throat washings of five of eight cases tested and failed to recover it from

four subjects not suffering from influenza. Sera obtained from either recovered ferrets or from patients after an attack of influenza neutralized the virus. All the evidence first presented and that obtained later pointed to the etiological importance of this virus in the disease.

The presence of Smith, Andrewes and Laidlaw's virus in epidemic influenza has been amply confirmed. Francis recovered it from cases of the disease occurring in Puerto Rico,¹¹ Philadelphia,¹¹ Alaska,¹⁷ and New York¹¹; Burnet isolated it from cases of influenza in Melbourne, Australia¹⁷; Brightman and Task found it in an outbreak among children in New Haven¹⁸; and Smorodintseff and his coworkers demonstrated its presence in an outbreak in Leningrad.¹⁹ Furthermore, Andrewes, Laidlaw and Smith, since their original discovery, have isolated a number of additional strains in England.²⁰ It is evident that the virus is widely disseminated.

The strains of influenza virus thus far obtained from man have appeared to be identical with one another so far as could be judged by cross-immunity tests and by neutralization tests with sera from recovered animals.^{20, 21, 27, 28} However, Magill and Francis, using virus-neutralizing serum prepared in a non-susceptible host, have recently presented evidence that the Puerto Rico and Philadelphia strains differ antigenically.²¹ Since these differences were not detectable when sera from recovered susceptible hosts were employed in the cross-neutralization tests, it seems that, for practical immunological purposes, the influenza viruses isolated from patients in various parts of the world must still be considered serologically quite a homogeneous group.

ACTIVITIES AND PROPERTIES OF HUMAN INFLUENZA VIRUS

Production of Pneumonia in Ferrets. Francis²² observed that, after several passages in ferrets anesthetized at the time of inoculation, the Puerto Rico strain of human influenza virus produced pulmonary consolidation in addition to the usual changes it had caused from the beginning in the upper respiratory tract. The pneumonias were of a bloody-edematous character and sometimes proved fatal. Similar passage of the original English strain resulted in its also acquiring the ability to produce pulmonary consolidation.²²

The Infection of Mice. About a year after the discovery that ferrets were susceptible to influenza virus, Andrewes, Laidlaw and Smith²³ and Francis²³ found that the ferret-adapted virus was also pathogenic for white mice. Administered intranasally to etherized mice, a well-adapted virus caused illness which usually terminated fatally after from three to seven days. At postmortem the only constant changes were in the lungs. These were deep red and almost airless except for small emphysematous areas at the periphery.

Immunity Conferred by Infection. Influenza virus was found to confer immunity upon the animals it infected. Recovered ferrets were not only

solidly immune to reinfection but their sera contained neutralizing antibodies for the virus^{17, 21}

Cultivation and Size of Influenza Virus The size of the influenza virus particle has been estimated to lie between 80 and 120 m μ on the basis of differential ultrafiltration through collodion membranes²⁵ and between 87 and 99 m μ as determined by centrifugation²⁶

The virus could not be cultivated upon ordinary bacteriological media although it grew readily in media containing minced chick embryo or upon the chorio-allantoic membrane of the developing hen's egg^{15, 27, 28} It is clear that, like other filtrable viruses, influenza virus requires living cells for its multiplication

COMPARISON OF THE VIRUSES OF HUMAN AND SWINE INFLUENZA

With the discovery of a virus in human influenza, the fortunes of the swine influenza virus took an unexpected turn It was found that the virus from swine was also pathogenic for ferrets and mice and that it caused a disease in these two animals which was indistinguishable clinically or pathologically from that produced by ferret-adapted human influenza virus^{12, 23 29 30} True, there were certain differences in the initial pathogenicity of the two viruses Thus, the swine influenza virus when administered intranasally to anesthetized ferrets induced pneumonia even in its first passage whereas the human virus required several serial passages in ferrets before it acquired the ability to cause pulmonary consolidation In like manner, swine influenza virus proved directly pathogenic for mice while the virus from man was pathogenic for mice only after it had been subjected to several serial transfers in ferrets^{*} It seems likely that these initial differences in the pathogenic activities of the two agents may be those due to "fixation" by prolonged sojourn in a foreign host since passage of human influenza virus through ferrets alters it in such a way that it becomes more like the swine influenza virus and less like the one originally obtained from man Human influenza virus, fully adapted to the ferret, produces a disease picture in ferrets and mice that is indistinguishable from that caused in these animals from the outset by swine virus

While influenza in swine is a disease of complex etiology and both the filtrable virus and *H influenzae suis* are essential to its causation, the disease in ferrets and mice appeared to be caused solely by the virus No evidence was obtained to indicate that *H influenzae suis* or any other bacterium modified the virus infection in these animals in any constant or significant manner^{12, 13, 23, 29, 30}

But the similarity between the swine and human influenza viruses did not end with their like pathogenicity for ferrets and mice It was found that they immunized against one another Thus ferrets or mice recovered from infection with swine influenza virus were not only immune to rein-

^{*} Francis and Magill have recently secured strains of influenza virus from man that "took" directly in mice without preliminary ferret passage¹⁶

fection with that agent but also usually resisted infection with the human influenza virus. In like manner, animals first infected with human virus were found later to be immune to the swine virus. Such cross-immunity suggested a close immunological relationship between the viruses from man and swine. That the two agents were not actually identical, however, could be shown by cross-neutralization experiments: they could be differentiated serologically.^{20, 20, 31} Each virus was completely neutralized by its homologous immune serum though the heterologous immune serum either failed to neutralize or neutralized only partially. The conclusion reached from consideration of cross-immunity and cross-neutralization experiments was that the viruses of human and swine influenza were related but not identical.

The swine influenza virus particle was found to have the same diameter as that of the human virus particle.²¹ Swine influenza virus was cultivable in media like that required by the human virus.^{21, 22}

THE SUSCEPTIBILITY OF SWINE TO HUMAN INFLUENZA VIRUS

The many similarities between human and swine influenza virus raised the question of whether the human agent might not be pathogenic for swine. This was studied experimentally first by Elkeles²³ and later by Shope and Francis.²⁴ It was found that swine, inoculated intranasally with human influenza virus alone, developed an extremely mild illness similar clinically and at autopsy to the flu-like disease caused by infection with swine influenza virus alone. When small amounts of a culture of *H. influenzae suis* were administered with the virus a more prostrating febrile illness usually resulted. This was similar to swine influenza although never so severe. At autopsy the pneumonia encountered was of the same character as that seen in swine influenza but much less extensive. The disease caused in swine by the human virus and *H. influenzae suis* could best be characterized as a mild swine influenza similar qualitatively but differing quantitatively from the typical disease occurring naturally in this species.

It was apparent from the work thus far described that the viruses of swine and human influenza were related but not identical. So far as our information went, the human virus, though capable of infecting swine, was probably specific for man, the swine virus was specific for swine.

But this view as to the species specificity of the two agents had to be modified when the influenza virus-neutralizing antibody content of human serum was studied.

ANTIBODIES TO HUMAN AND SWINE INFLUENZA VIRUS IN HUMAN SERA

Smith, Andrewes and Laidlaw^{1, 22} had shown that the sera of persons convalescent from influenza neutralized the human virus. Later Francis and Magill,²⁴ by comparing the antibody content of sera drawn during the acute stage of influenza with that obtained after recovery, demonstrated

that neutralizing antibodies for human influenza virus actually developed during an attack of the disease. From this it seemed likely that their presence in the serum of an individual was an expression of a previous infection with human influenza virus.

Sera from persons of different ages have been studied for their ability to neutralize human and swine influenza virus. The findings obtained in England by Andrewes, Laidlaw and Smith³⁰ and those gotten in this country by Francis and Magill⁴ and Shope³⁵ were in close agreement. Arranging the cases in three broad age groups it was found, in the English experiments, that the human virus was significantly neutralized by 62 per cent of the sera from persons over 20 years of age, by 57 per cent of the sera from people between 10 and 19 years old and by 33 per cent of the sera from children under 10 years. In the American experiments the human virus was completely neutralized by 48 per cent of the sera from individuals over 20 years of age, by 58 per cent of the sera from people between 10 and 19 years and by 49 per cent of the sera from children under 10 years. It can be seen from these data that, with the exception of the children in the English group, roughly half of the human sera studied neutralized human influenza virus. The incidence of antibodies encountered does not seem surprisingly high in view of the known recent widespread prevalence of the influenza virus.

But the results obtained in the corresponding experiments with swine influenza virus were unexpected. It was found, in the English experiments, that the swine virus was significantly neutralized by the sera from all persons over 20 years of age, by 66 per cent of the sera from individuals between 10 and 19 years but by none of the sera from children under 10 years. In the American experiments the swine virus was completely neutralized by 92 per cent of the sera from persons over 20 years of age, by 63 per cent of the sera from individuals in the 10 to 19 year age group but by only 11 per cent of the sera from children under 10 years. These results were surprising in two respects. First, it was unexpected to find that practically all adult human sera contained antibodies capable of neutralizing a virus that was supposedly specific for swine. Second, since the antibodies were so uniformly present in sera from adults it was surprising indeed to find that they were almost completely lacking in the sera of children. An interpretation of the significance of the findings was difficult because no strain of influenza virus immunologically like the one from swine had ever been recovered from man. The question will be considered more fully later.

DISCUSSION

In considering all of the work thus far done in determining the etiology of influenza in man one is struck by the fact that it can be divided both chronologically and by subject matter under most intense investigation into two main periods. During the first period which extended roughly from the 1889-1890 pandemic through the 1918-1920 pandemic, the interests of

investigators were largely bacteriological and were centered upon the problem of elucidating the rôle played by Pfeiffer's *H. influenzae* in the disease. During the second period which may be dated from the time of the discovery of a virus in the disease by Smith, Andrewes and Laidlaw up to the present, practically all investigative work has been focused upon the role played by this new virus. There has been very little overlapping in the subjects under most intensive study during each of these two periods.

Between the bacteriological and the virus periods of human influenza, investigation into the etiology of swine influenza revealed this disease to be caused by the concerted action of a bacterium like Pfeiffer's bacillus and a filtrable virus. Not only was the swine bacterium like Pfeiffer's bacillus, but experience with it during the first three years' work, in attempting to determine its etiological relationship of swine influenza, closely paralleled the experience investigators of human influenza had had with Pfeiffer's bacillus during the bacteriological period^{11, 16}. The arguments for and against considering *H. influenzae suis* etiologically important in swine influenza were much the same as those already debated for many years regarding the causal role played by *H. influenzae* in human influenza. Furthermore, the viruses of swine and human influenza were subsequently found to be strikingly alike though not identical. Here then, in the etiology of swine influenza, was what seemed to be a connecting link between the two periods of human influenza investigation—a compromise between Pfeiffer's bacillus on the one hand and a filtrable virus on the other which accepted both as etiologically essential.

But is it justifiable to apply knowledge gained in the study of swine influenza to human influenza? An answer to this question depends partly upon the significance assigned to the swine influenza virus-neutralizing antibodies found in human sera. Two hypotheses to explain the presence of these are apparent. One would interpret them as specific, the other as non-specific, in the sense that, respectively, they had or had not resulted from past infection with swine influenza virus. The non-specific hypothesis will be considered first.

It is known that experimental animals repeatedly exposed to human influenza virus sometimes develop antibodies capable of neutralizing both the human and the swine viruses¹¹. Perhaps the swine virus antibodies in human sera were non-specific in the sense that they had been established not by virtue of previous infection with swine influenza virus but rather had resulted from repeated previous exposures to human influenza virus. If this were the correct explanation then all human sera which neutralized the swine virus should also neutralize the human agent. Comparison of duplicate tests against the two types demonstrated clearly that this was not the case. Antibodies neutralizing swine virus were frequently present in human sera which failed to neutralize human virus. In these it was evident that the neutralizing antibodies for swine influenza virus had not resulted from previous infection with human virus, unless one chose to believe that the

specific antibodies for the human virus disappeared after each influenzal infection while the non-specific swine virus antibodies persisted and were gradually built up by each succeeding attack of influenza. There are as yet no data to indicate that this conjecture is likely or even possible.

The hypothesis which interprets the swine virus-neutralizing antibodies in human sera as specific and to have resulted from past infection with a virus whose antigenic composition was similar to that of swine influenza, just as the human virus antibodies are considered to reflect a past infection with human influenza virus, is more in harmony with the facts determined by animal experimentation. On the basis of this interpretation it is apparent that human sera contain neutralizing antibodies for at least two immunologically distinct types of influenza virus. One is the current human virus of Smith, Andrewes and Laidlaw known to be widely prevalent in man at the present time. The other, antigenically like swine influenza virus, is unknown and has never been detected in man. It has, however, left ample evidence of its past widespread prevalence in the form of neutralizing antibodies in the sera of almost all adult human beings. That it is no longer widely existent in the human population is indicated not only by the failure of investigators to recover it from cases of influenza during the past four years, but by the almost complete absence of antibodies for it in the sera of children. If one ascribes a specific character to the swine virus-neutralizing antibodies in human sera, the conclusion that this unknown human virus was indeed swine influenza virus, or a closely related agent, is inescapable.

However, there is no direct evidence that the swine influenza virus, as we know it today, is capable of infecting man. Indeed, indirect evidence indicates that it does not infect man because, while swine influenza has occurred annually since 1918, our serological evidence suggests that the human prototype of swine influenza virus ceased infecting man generally 10 or more years ago.

The most apparent interpretation of these findings is that the swine virus represents a surviving form of an extinct or temporarily quiescent human influenza virus which has become so "fixed" in swine as to be no longer pathogenic for human beings. If this is the case, then the history that swine influenza appeared for the first time in 1918 serves to date the time of prevalence of this vanished human virus. The experimental and historical facts seem best explained, for the present at least, by the theory that the swine influenza virus represents a surviving form of that pandemic in man in 1918, as already suggested by Laidlaw³⁷. On this basis, the presence in human sera of antibodies neutralizing swine virus would be considered to indicate that the donors of these sera had undergone immunizing exposures to, or infections with, an influenza virus of the 1918 pandemic type. Thus it seems possible that swine influenza may represent more than merely an interesting analogue of the human disease, it may actually bear a relationship to pandemic influenza.

The matter of determining the relationship between the influenzas of swine and man is of importance only in so far as it bears upon the question of the etiology of the human disease. The causative agents of the swine disease are known. Furthermore, agents of a similar nature are present in the human disease. Do these agents play the same rôle in pandemic human influenza that they are known to play in swine influenza? I have purposely, in this paper, called attention to the close similarity that exists between the disease pictures of influenza in swine and pandemic influenza in man, to the suggestive history that swine influenza made its first known appearance during a great human pandemic, to the apparent identity of the predominant bacterium in the human disease with the one known to be etiologically essential in the swine disease, to the close relationship between the viruses of human and swine influenza, and to the presence in human sera of neutralizing antibodies for both the human and swine viruses. Any one of the parallelisms might be fortuitous, it seems unlikely that all should be.

The possibility must, of course, be kept in mind that human beings may resemble ferrets and mice more closely than they do swine in their reaction to influenza virus. In this event the virus would be considered the sole and primary etiological agent of influenza and any associated bacteria would be thought of as merely concomitant and of secondary importance. However, the disease caused in ferrets and mice by the human influenza virus alone may be just as highly artificial in reflecting the complete etiology of human influenza as is that caused in the same animals by swine influenza virus alone in reflecting the complete etiology of the swine disease. It remains to be determined whether pandemic influenza in man is a disease like that in ferrets and mice caused by infection with the virus alone or whether it resembles swine influenza and requires both the virus and a bacterium. Personally, I am of the opinion that the virus of human influenza, like that of swine influenza, constitutes only a partial etiology of the disease in which it is involved and that workers of the bacteriological period who contended for the etiological importance of Pfeiffer's bacillus may have been at least partially right.

CLINICAL INVESTIGATIONS OF INSULINS WITH PROLONGED ACTIVITY

By RUSSELL M WILDER, Ph D , M D , F A C P , *Rochester, Minnesota*

A YEAR ago, at the meeting of the American College of Physicians, Dr Joslin expressed the opinion that Hagedorn by effectively retarding the action of insulin with protamines had opened a new era in the treatment of diabetes. During the past year hundreds of physicians have had the opportunity to use protamine insulin in the treatment of diabetes, and I am informed that their verdict is almost unanimously favorable. In February of this year an improved modification of Hagedorn's preparation was placed on the market. It already had received the official endorsement of the Insulin Committee in Toronto and that of the Council on Pharmacy and Chemistry of the American Medical Association.

I propose in this paper to recount certain clinical investigations which illustrate some of the peculiarities of the action of insulins with retarded activity, and in part explain the advantages attending their use.

A pitfall to be avoided when studying the effect in diabetes of drugs and diets, is the trial of the remedy in cases in which the diabetes is of short duration. This mistake in the past has led to a number of erroneous conceptions, the notions, for instance, that dark breads can be tolerated better than white breads and that honey and maple sugar are less harmful than other sweets. Quackery in diabetes thrives because of the tendency for spontaneous remission in the early course of this disease. Tolerance for carbohydrate improves during the first year or two, if only minor attention is paid to limiting the intake of carbohydrate, and the credit is given, undeservedly, to the medicine used or the special food. The patients who kindly consented to serve as subjects for these clinical investigations had had diabetes for five years or longer.

Mild diabetes also can mislead the observer, by fluctuating in intensity. Furthermore arteriosclerosis and certain other complications of diabetes sometimes decrease the sensitivity of the patient to overdoses of insulin, and under these circumstances enough unmodified insulin may be administered in one injection to prevent hyperglycemia for 24 hours. Because of this fact we chose patients who were hypersensitive to overdoses of insulin, they previously had been more or less refractory to satisfactory control, and most of them were "pedigreed," in the sense in which Dr Woodyatt has used this term, that is, they had been studied before, some of them many times, so that the characteristics of their disease were known.

* The Trimble Lecture, Medical and Surgical Faculty of the State of Maryland, Baltimore, Maryland, April 28, 1937, also presented in part to the American College of Physicians, St. Louis, Missouri, April 19, 1937, under the title "Protamine and Other Long-Acting Insulins."

The work to be presented represents the combined efforts of several of us. My associates include Drs Edwin J Kepler, Edward H Rynearson and Jesse Bollman, and the following Fellows of The Mayo Foundation for Medical Education and Research: Randall C Sprague, Benjamin B Blum, Bertha M Davis Clark, Reid R Heffner, Clarence W Erickson, James A Barr, Donald W Ingham and George R Crisler. For the necessarily arduous analytical work we are indebted to Dr Arnold E Osterberg and members of his department, and for much assistance our thanks are due to Miss Mary A Foley, Sister Mary Victor, Sister Rebecca and others in the dietetic and nursing departments of the St Mary's and Kahler hospitals. The preparation of protamine insulin came from the Eli Lilly Company of Indianapolis, the crystalline insulin was supplied by Stearns and Company of Detroit.

THE PROLONGED ACTION OF PROTAMINE INSULIN

Our first observation revealed that the claim for prolongation of action of protamine insulin was fully warranted (figure 1). A woman aged 49

FIG 1 Comparative duration of action of ordinary insulin and protamine insulin

years, who had had severe diabetes for nine years, was given 35 units of unmodified insulin 20 minutes before breakfast. The breakfast contained 30 gm of carbohydrate, 18 gm of protein, and 44 gm of fat. The level of the blood sugar fell from its fasting value of 370 mg per 100 cc and

reached a minimum of 150 mg per 100 c c in six hours. The noon and evening meals were withheld, and no more insulin was used. The value for the blood sugar rose as rapidly as it had fallen. By the following morning it stood at 425 mg per 100 c c and the value for the carbon dioxide combining power of the plasma was 28 volumes per cent. One cannot say with certainty at just what hour, in this observation, the action of the insulin terminated, because a blood sugar time curve is an expression of several variables. However, it is reasonable to regard the point at which the curve rose above the renal threshold for dextrose (about 180 mg) as marking the end of the action of insulin. By this arbitrary standard, the 35 unit dose, in this case, acted for eight hours.

On another day, with conditions as nearly identical as possible, an equal dose of plain protamine insulin was followed by an increase in the value for the blood sugar after breakfast from 400 to 449 mg per 100 c c. Then a prolonged fall occurred. The low point, 72 mg per 100 c c, was reached 18 hours after the injection, and the next morning there still was evidence of the activity of insulin. The value for the blood sugar then was only 148 mg per 100 c c, and glycosuria and evidence of acidosis were absent.

This observation, and others to be described, led us to anticipate that protamine insulin might be given in one dose each 24 hours. Especially should this be possible if the injection was made in the morning, so that the peak effect would come at the proper time to be buffered by the hyperglycemic effect of food eaten during the day. We put this plan of treatment to trial, and soon were convinced of its desirability. The same plan has been adopted in Toronto and elsewhere. The convenience to the patient of being able to take in the morning all the insulin he needs for the day is not inconsiderable. In milder cases protamine insulin alone has been used, in more severe cases a supplementary dose of an insulin with prompter action has been necessary.

COMPARATIVE ACTION OF PLAIN, CALCIUM, AND ZINC PROTAMINE INSULINS

Soon after the introduction of protamine insulin it became apparent that the stability of the precipitate would have to be increased before it could be made available commercially. Suspensions of the original preparation, after standing for several days, would lose some of their potency, due to adherence of the precipitate to the sides of the bottle. The manufacturers overcame the difficulty by adding small amounts of soluble salts of calcium (1 or 2 mg of calcium per 100 units) or of zinc (1 mg of zinc per 500 units). The additions, it was found, also changed the duration of action of the insulin. Calcium shortened the period of action, while zinc had the opposite effect. Zinc also formed a more stable precipitate. It is for these reasons it now is regularly incorporated in the preparation which has been placed on the market.

The relative intensity and duration of action of protamine insulin with and without additions of calcium or zinc are illustrated (figure 2). The subject of these observations was a girl, aged sixteen years, who had been diabetic for 10 years and required about 80 units of unmodified insulin daily. In each observation 50 units of the preparation to be studied were injected and food was withheld for the next 48 hours. Between each study the patient was treated for several days with unmodified insulin, the last dose being given 14 hours before the start of the next injection of a protamine preparation. Thus, a high value for the fasting blood sugar was insured, and the durations of action of the various preparations could be compared under similar conditions. At the forty-eighth hour after the administration

FIG. 2. Comparative duration of action of plain, calcium, and zinc protamine insulins.

50 units of plain protamine insulin, activity was almost spent, the blood sugar curve had risen to the renal threshold. At the forty-eighth hour after the administration of an equal dose of protamine insulin containing 1 mg of zinc per 500 units, the value for the blood sugar was still near minimal point, which was evidence of continued strong action of insulin. When 50 units of the preparation containing 1 mg of calcium per 100 units were given, the value for the blood sugar passed the renal threshold by the twenty-eighth hour.

STUDIES OF PROLONGED HYPOLYCAEMIA

Many a diabetic, using unmodified insulin, has had insulin reactions during his sleep, with only a headache or sore muscles or a bitten tongue the following morning to inform him of the episode. The spontaneous recovery

attributable to the fact that the action of unmodified insulin is spent in a relatively few hours and hepatic glycogenolysis begins as soon as the insulin is exhausted. The prolonged action of protamine insulin made it seem possible that a resulting hypoglycemia might not be recovered from spontaneously, and we became apprehensive for patients who, using protamine insulin, might fail to get their food. An attack of migraine, for instance, might interfere with the retention of food and have serious consequences. Therefore, the duration and severity of the hypoglycemia produced by protamine insulin in patients who fasted were made the subject of investigation.

FIG 3 Prolonged hypoglycemia from administration of protamine insulin to a fasting diabetic subject

In one study (figure 3) a young man, who had been a diabetic for six years, received 70 units of plain protamine insulin. This dose previously had been given every morning and was what was required to prevent glycosuria. The value for the blood sugar at the time was 94 mg per 100 cc. It fell gradually to a low level of 45 mg and remained between 45 and 62 mg for the last 38 hours of a fast of 57 hours. There were no notable symptoms until late. In the fifty-second hour the patient became restless and irrational, the tendon reflexes were exaggerated, the pupils were dilated, and the value for the systolic blood pressure rose to 150 mm of mercury from previous readings of about 120 mm. The condition of the patient was much improved 10 minutes later by the injection of 1 cc of a 1:1000 solution of epinephrine, although the values for the blood sugar, determined at intervals of 15 minutes after administering the epinephrine, had not changed significantly. The fast was terminated in the fifty-seventh hour because of the reappearance of symptoms.

This observation, and others like it, showed that when hypoglycemia is produced very gradually it may not be attended by the stormy symptoms characteristic of the reactions to unmodified insulin. Subsequent experience has confirmed this conclusion. If a patient rests in bed, after overdoses of protamine insulin, symptoms may be absent entirely or appear very late. If he is up and about they are more likely to be manifest because exercise provokes them. As a rule, however, they differ from those with which patients and physicians, using unmodified insulin, have become familiar. The phenomena which probably have been attributed correctly to a protective mobilization of epinephrine are less pronounced. The value for the blood sugar falls so gradually that the suprarenal glands are not aroused. Therefore, tremor, sweating, tachycardia and pounding pulses usually are missing, and their place is taken by symptoms of cerebral origin, such as lassitude, fatigue, headache or nausea.

It appeared from studies like the one I have cited (figure 3) that loss of consciousness was less likely to occur after the use of protamine insulin, and that hypoglycemia could be tolerated for many hours without serious consequences. This was reassuring. However, symptoms of cerebral irritation were apparent before the termination of the fast, and we have found (Bollman) that dogs made hypoglycemic for several days with protamine insulin would die of convulsions when dextrose was given to restore them. Multiple petechial hemorrhages were scattered throughout the brains of these animals. Therefore, it was not to be concluded that long-continued hypoglycemia was harmless, and we were led to recommend that patients take sugar at intervals of half an hour if meals were missed or whenever unusual symptoms suggested overdosage. Experience later revealed that hypoglycemia may return after treatment or even after meals, and therefore the patients were advised that the doses of sugar administered at intervals of half an hour were to be resumed if the symptoms returned.

THE EFFECT OF THE TYPE OF DIET ON THE CONTROL OF GLYCOSURIA

There has been much difference of opinion as to what type of diet gives the best results in the practical management of diabetes. Many physicians have followed the recent trend toward allowing relatively large amounts of carbohydrate. Others have adhered to the principles established by Naunyn, and are keeping the intake of carbohydrate low. Others have taken the middle road, planning diets with greater reference to general nutritional considerations.

Two young men, aged 18 and 20 years respectively, who had diabetes of maximal severity, were given first low and later high carbohydrate diets and single morning injections of protamine insulin (figure 4). In each case the loss of dextrose in the urine was considerably greater after administration of the high carbohydrate diet than it was after administration of the low carbohydrate diet, as was the average of the five blood

sugar determinations made each day. The average level of the morning blood sugar, on the other hand, was lower during the days on which the high carbohydrate diets were administered. These postabsorptive levels were so low, indeed, that it was impossible without provoking reactions to use larger doses of protamine insulin in an attempt to control the daytime hyperglycemia and glycosuria. This and other experience has dissuaded us from resorting to diets containing more than about 150 gm of carbohydrate when patients are treated with protamine insulin. Some patients,

FIG 4 Comparative effect of low and high carbohydrate diets in patients treated with protamine insulin

however, do well with more liberal amounts, as is illustrated by the following observation (figure 5)

A diabetic woman, aged 47 years, who required 50 units of protamine insulin on a measured diet containing 140 gm of carbohydrate, was given 60 units a day and served food from the general kitchen. Only candy and table sugar were withheld. On the first day of the general diet, 14.2 gm of sugar were excreted in the urine, but on the days that followed there was never more than a trace of sugar. This patient probably represented the type of adult diabetic whose blood sugar is not easily depressed below normal levels by unnecessarily large amounts of insulin. On the basis of the result, it would appear that in cases of the insulin-insensitive type of diabetes greater latitude in the amounts and quality of food may be permissible with the use of protamine insulin. Subsequent experience has confirmed this conclusion, although this type of treatment is not recommended.

OBSERVATIONS OF THE ACTION OF CRYSTALLINE INSULIN

About a year ago announcement was made of prolonged hypoglycemic action obtained with solutions of crystalline insulin. Since then, other reports have led to the assumption that the action of this crystalline insulin is comparable to that of protamine insulin. Our experience is different. We have been supplied with the material through the courtesy of the in-

ventor of a commercial method for its production, and our studies show that while its action is longer than that of unmodified insulin it is not long enough to permit treatment of severe diabetes with fewer injections than two a day. The preparation cannot take the place of protamine insulin, on the other hand, either this preparation, or one with a similarly intermediate duration of action, would be useful as an adjunct in the treatment of certain diabetic patients.

I already have stated that when diabetes is severe, sugar often appears after meals unless supplementary, quick-acting insulin is given with the morning dose of protamine insulin. The degree of glycosuria observed under these circumstances may be harmless, but until we have proof of its harmlessness we must insist on its control. This means using supplementary insulin, and for this purpose an insulin with action like that of

FIG 5 Treatment with unrestricted diet and protamine insulin

crystalline insulin would be very useful. Ordinary unmodified insulin is not satisfactory because its action is spent too early. The preparation of crystalline insulin that we have studied represents exactly what is needed. Its action is long enough so that when it is injected in the morning, together with the dose of protamine insulin, it amplifies the hypoglycemic effect during the day and prevents glycosuria after meals. By evening, however, its action has been spent, and thus the hypoglycemic effect of the protamine insulin is not exaggerated during the night.

An ideal insulin would be one which combined the activity of the right dose of protamine insulin with that of the right dose either of crystalline insulin or a preparation of similar behavior. Unfortunately, a good many difficulties stand in the way of achieving this. One patient would require more of the quick and less of the slow action, while another would need

more of the slow and less of the quick action. Such an insulin, therefore, would have to be "tailor-made" for the individual, as Dr. Campbell has suggested. A more likely solution of the difficulty may be expected from the preparation of a protamine insulin to which a quick-acting insulin can be added as required. At present, protamine insulin contains an excess of protamine, and thereby unmodified insulin which is added to it is precipitated. Possibly a way can be found to overcome the necessity for this excess. Until then, if supplementary doses of quick-acting insulin are to be given, the patient must take these separately, using a clean syringe for each injection.

I am showing data bearing on the duration of action of preparations of crystalline insulin, partly because of the interest in this subject and also because these data provide other information of practical significance in the treatment of diabetes.

An experiment I have described (figure 1), in which a single dose of insulin was given in the morning followed by breakfast but no other meals, was repeated several times to determine the relative duration of action of crystalline and protamine insulin. The volunteer diabetic patient who served in the first study of this type also consented to serve as the subject of these later studies. Before each observation she was maintained with unmodified insulin for a period of three days to avoid any holdover effects from previous injections of protamine insulin. In each observation the dose of insulin was the same, 35 units, and the breakfast always consisted of 30 gm of carbohydrate, 19 gm of protein and 44 gm of fat. It represented the breakfast of her maintenance diet.

In the observation of January 11 to 12, the insulin used was a solution of a special crystalline insulin. The blood sugar time curve is shown in figure 6. The data reveal that the insulin was spent before the twentieth hour. By the twenty-fourth hour signs of impending acidosis were present. In the observation of January 15 to 16 (figure 6) protamine zinc insulin was used in the same dosage (35 units). This produced an equal degree of hypoglycemia, more tardily, but maintained the blood sugar at a low level until after the twenty-eighth hour. Also, no sugar appeared in the urine until the fortieth hour, and there were no signs of acidosis until the forty-fourth hour.

These data illustrate what I have said, namely, that the action of the crystalline preparation is retarded considerably more than is that of unmodified insulin, but that the retardation of crystalline insulin is not comparable to that of protamine insulin.

PROTEIN WASTAGE PREVENTED WITH PROTAMINE INSULIN

In an observation made January 22 to 23, the patient who had been the subject of the observations of January 11 to 12 and January 15 to 16 was given 35 units of the preparation of crystalline insulin used before. In-

stead of a breakfast, however, followed by prolonged fasting, she received food every two hours. The feeding consisted of a mixture of milk and cream, so arranged that each feeding would supply amounts of carbohydrate, protein and fat comparable to a twelfth of the amounts of these food factors in the maintenance diet. The data are recorded in figure 7. It was observed that the duration of hypoglycemia did not exceed 12 hours, that sugar appeared in the urine by then, and that after 16 hours the excretion of nitrogen was greatly increased.

The observation made on January 22 to 23 was repeated February 5 to 6, with a preparation of crystalline insulin to which zinc had been added (figure 8). The course of events was almost the same as it had been before, although the action of the insulin was intensified slightly and con-

FIG. 6 Comparative duration of action of a special crystalline insulin and protamine zinc insulin

tinued about four hours longer. Even so, evidence of insulin activity had passed by the sixteenth hour. The value for the blood sugar was increased, the urine contained sugar and the excretion of nitrogen was increased.

Attention is invited to the behavior of the metabolic balance for nitrogen in these studies. The inflow of the nutrient at a continuous rate, accomplished by feeding the mixture of milk and cream at two-hour intervals, and the collection of urine at intervals of exactly four hours, made it possible to obtain this balance for a succession of four-hour periods. The patient at the beginning of each study had been given no insulin for 14 hours, and that insulin was unmodified insulin. No long-acting insulin had been used for several days, and since the case was one of severe diabetes, insulin action at the beginning of each study probably was minimal.

The negative balance for nitrogen of the first four-hour period in both studies is accounted for, I believe, by this circumstance. The sparing effect on protein of insulin given at the beginning of each study was not evident until after the first period. This delay is readily explained by the time necessary for absorption of the insulin. The effect of this insulin shows itself in the diminished excretion of nitrogen in the second, third and fourth periods. As the observations proceeded, a time was reached in each study when the excretion of nitrogen again rose and a negative

FIG 7 Negative nitrogen balance before and after period of activity of a dose of crystalline insulin

balance again was observed. This time coincided roughly in each case, with the time when the blood sugar curve rose above the renal threshold for dextrose.

The behavior of the balance for nitrogen in these studies would have escaped detection except for collection of the urines in four-hour periods, and the analysis of these separately for their content of nitrogen. Examinations of 24 hour collections would not have indicated negative balances for nitrogen, for the reason that the loss of nitrogen during the periods when

insulin was inactive would have been offset by the retention of nitrogen in the other periods

Negative balances for nitrogen have long been observed in cases in which severe diabetes is out of control, the condition formerly was called "azoturia," but so far as I know, it has not been demonstrated before that azoturia occurs so soon after the period of activity of a preceding dose of insulin. The phenomenon is not without practical importance. Patients treated with unmodified insulin are commonly given one dose before each

FIG 8 A longer period of activity was imparted to crystalline insulin by the addition of zinc, negative nitrogen balances occurred before and after period of insulin activity

meal, or two doses, one before breakfast, the other before supper. The time of action of unmodified insulin is not more than eight hours, and under these circumstances the balance for nitrogen may become negative for one or more short periods in each 24 hours. In these periods the protein of the body is subjected to drainage of its amino-acids to supply material out of which the liver can manufacture sugar. Intracellular as well as deposit-protein may be drawn upon, to judge from the increased excretion of creatine and creatinine which was observed when the balance for nitrogen was negative in the studies mentioned (figures 7 and 8)

It has been a common observation of those who have had experience with protamine insulin that patients receiving preparations of it gain in strength and fitness. Improvement has been noticeable, particularly in individuals who previously, using unmodified insulin, were not perfectly controlled. It is not always possible with protamine insulin to obtain complete control in cases of severe diabetes, but even when the control with protamine insulin is imperfect the patients say they feel better, and gradual improvement in tolerance for carbohydrate may be observed. I suggest that the reason for the improved sense of well-being of such patients and the improvement in their tolerance may be attributable to the avoidance of intermittent periods of azoturia.

FIG 9 A dose of protamine zinc insulin, which was too small to control glycosuria, prevented significant loss of nitrogen for 32 hours

This hypothesis is supported by the following evidence. In an observation made February 1 to 2 (figure 9), planned exactly like those of January 22 to 23 and February 5 to 6, protamine zinc insulin was given. The same patient submitted to the observation and the number of units of insulin which were administered was the same. Again, a negative nitrogen balance was observed in the first four-hour period. The amount of protamine insulin was not enough to lower the blood sugar below the level at which it was found in the morning. It, therefore, was inadequate to suppress glycosuria and yet the excretion of nitrogen was depressed after the first four hours, it remained below the level of the intake of nitrogen until the end of the twentieth hour. The balance was still not grossly negative even after 31 hours.

Similar data were obtained in another study. The patient in this case was a young woman who had diabetes of extreme severity. It antedated the introduction of Banting's insulin. Protamine insulin containing calcium was given in two observations (figure 10 and 11) and zinc protamine insulin was given in a third (figure 12). A protein sparing effect was evidenced each time by diminished excretion of nitrogen after the first period. With the preparations containing calcium the sparing effect lasted for only 24 hours, but with the preparation containing zinc it was still apparent in the period between the thirty-second and thirty-sixth hours. In this last

FIG. 10 An injection of protamine insulin with added calcium inhibited excretion of nitrogen for 24 hours, the period of activity was followed by azoturia

period the value for the blood sugar stood at almost as high a level as it had in the beginning of the experiment, and 16 gm of sugar were excreted in the urine.

The results of these observations also bear on the question I raised before, whether glycosuria after meals is harmful when patients are treated with protamine insulin. They show that moderate glycosuria under these circumstances is not attended with azoturia, which may mean that such glycosuria is not as harmful as that which occurs in intervals between the periods of activity of doses of unmodified insulin. The prevention of pe-

moderate azoturia by the use of protamine insulin may even mean that those degenerative disorders which so frequently complicate diabetes—retinitis, neuritis, and arteriosclerosis—will occur less frequently, or if present, will develop less rapidly, but more time must pass before this can be determined.

PROTAMINE INSULIN IN THE TREATMENT OF DIABETIC ACIDOSIS

A final topic demanding brief mention is the use of protamine insulin in the treatment of diabetic acidosis. It was the general belief a year ago

FIG 11 An injection of protamine with added calcium inhibited excretion of nitrogen for 24 hours

that the retarded action of the new insulin made it undesirable for use in emergencies. My associates and I now are convinced that this opinion is mistaken, and that a dose of protamine zinc insulin used together with quick-acting insulin, is of advantage. A report of some of our experiences with this has already been made by Kepler, Ingham and Crisler. The slow absorption of protamine insulin guarantees a continuous supply of insulin to the circulation. Thus, continuous action is effected no matter how rapidly insulin may be exhausted after it enters the circulation. A continuous insulin effect is difficult to obtain in acidosis by injecting unmodified insulin.

at intervals such as usually are chosen, for the reason probably that insulin after its absorption is destroyed more rapidly than usual. Our practice now is to give protamine insulin at the beginning of treatment, in a dose of from 50 to 100 units, and thereafter to treat the patient in the conventional manner with the multiple doses of unmodified insulin that are suggested by frequent tests of the blood and urine. We have treated seven patients who had diabetic acidosis, in this way, and the results have been surprisingly satisfactory. The doses of unmodified insulin found necessary in all but one case have been much smaller than expected, the time required to restore

FIG 12 An injection of zinc protamine insulin inhibited loss of nitrogen for 36 hours, despite the hyperglycemia and glycosuria which occurred after the twenty-eighth hour

the patient has been shortened, and the period of continued insensitivity to insulin, which usually is encountered after attacks of acidosis, has been avoided. Possibly we have had a series of unusually favorable cases, but I am quite sure this is not the entire explanation. The patients in two instances were in profound coma.

The data in the last case of acidosis, at this writing, are shown (table 1). The patient was 59 years of age. The recent statistical data on diabetic acidosis reported from the clinic by Dr. Baker and from the Deaconess Hospital by Dr. Joslin and his associates, show a mortality of about 40 per

cent for patients in the sixth decade who require treatment for acidosis. Diabetes had been present for five years and the dose of insulin had been 40 units daily (two injections daily, each of 20 units of unmodified insulin). The attack was precipitated by the failure of the patient to take insulin. I am thankful to say that she was not a graduate of our diabetic school. She accompanied a relative and was not intending to consult us about herself. She became fatigued on a Sunday, by a long automobile journey, was disinclined to eat supper and omitted the dose of insulin. She was nauseated on Monday, and omitted meals and insulin. She took 20 units of unmodified insulin on Tuesday morning, but none that evening. She began to vomit during the night, and on Wednesday morning called a physician. She was drowsy on admission to the hospital, but not unresponsive. Her breath smelled strongly of acetone and the respiration was markedly hyperpneic. The skin and tongue were dry. Extreme thirst and abdominal pain were the chief complaints. The balance of the story is told by the data in the table. Suffice it to add that this patient was so well by the fifth day that no amount of insistence could dissuade her from leaving the hospital.

SUMMARY

Selected observations have been presented to illustrate some of the peculiarities of the action of preparations of protamine and crystalline insulins. Conclusions based on these and other studies are as follows:

The activity of protamine insulin is prolonged for more than 48 hours

in fasting diabetic patients. The period of activity of unmodified insulin is less than 12 hours in fasting patients.

Further prolongation of action has been effected by the amount of zinc contained in the preparation of protamine insulin recently placed on the market. The addition of calcium shortens the duration of activity.

Symptoms may be absent for many hours in fasting patients who are made severely hypoglycemic by the administration of protamine insulin. When symptoms finally appear they are likely to be limited to those of cerebral origin, such as lassitude, fatigue, headache, and nausea.

Greater instability of the level of the blood sugar adds to the difficulties of treatment with protamine insulin, when much carbohydrate is included in the diet. This may not be true in cases of the type of diabetes characterized by insensitivity to overdoses of insulin.

The duration of action of solutions of previously crystallized insulin is intermediate. It does not extend beyond 12 or 14 hours when patients receive food. The duration of action of protamine insulin when food was given exceeded 36 hours.

The experimental data presented illustrate the importance of insulin in protecting the proteins of the body from catalysis. They reveal, furthermore, that in severe cases of diabetes, azoturia and creatinuria were only restrained during the period of activity of the dose of insulin injected. Therefore, it appears that when exclusive dependence is placed on multiple doses of an insulin which has an action of short duration, intervals may occur in each 24 hours when the balance for nitrogen will be negative. If unmodified insulin is used this can only be prevented by spacing doses more closely than has been customary. Such periodic intervals of azoturia are not encountered when an insulin is used which has an activity extending for more than 24 hours, and I have suggested that the continuous protection of the proteins of the tissues affected by this means may account for the improved healthiness and apparent gain of tolerance of patients using protamine insulin.

Finally, I also have directed attention to the usefulness of protamine insulin in the treatment of diabetic acidosis. Here again, its value seems to depend on the continuity of the insulin activity obtained.

THE HEMOPOIETIC LIVER PRINCIPLE

By G E WAKERLIN, M D , Ph D , F A C P , *Louisville, Kentucky*

THE hemopoietic liver principle is also known as the anti-pernicious anemia principle and the erythrogenic liver principle. As you are aware, the interaction in the gastrointestinal tract of an as yet unidentified constituent of the gastric juice, called the "intrinsic factor," with some dietary component associated with protein, known as the "extrinsic factor," forms a third substance which is absorbed via the portal circulation and stored in the liver where it is very likely further elaborated. This substance, the hemopoietic liver principle, is then released to the bone marrow where it brings about the normal maturation of the red blood cells from the megaloblastic to the normoblastic stage. The term, anti-pernicious anemia principle, implies that the substance is pharmacologic rather than physiologic in character. Furthermore, the principle is effective in the treatment of various macrocytic, hyperchromic anemias other than pernicious anemia. The term, erythrogenic liver principle, is too limited inasmuch as the substance also appears to stimulate the formation of granulocytes and thrombocytes, as well as the maturation of the red blood cell. Hence the term, hemopoietic liver principle, appears to me to be the most appropriate. In this discussion, I shall deal briefly with some features of the chemistry, bioassay physiology and pathological physiology of the hemopoietic liver principle.

Since the demonstration of the effectiveness of liver in pernicious anemia by Minot and Murphy ¹ in 1926, the chemistry of the hemopoietic liver principle is being slowly unfolded. As a result of the early work of Cohn and his coworkers ² in 1927 leading to the preparation of a potent liver extract suitable for oral administration, it became apparent that the hemopoietic principle was relatively heat-stable, soluble in water and 70 per cent ethanol, relatively insoluble in 95 per cent ethanol, and insoluble in ether. In 1928 Cohn ³ further purified his liver extract so that 0.6 gm per day orally was as effective as 250 gm of whole liver in the treatment of pernicious anemia. At this time, Cohn considered the active principle to be either a nitrogenous base or a polypeptide. In 1930, Gansslen,⁴ Cohn,⁵ and Castle⁶ prepared liver extracts of sufficient purity to be administered parenterally. Cohn then regarded the hemopoietic liver principle as a secondary or tertiary amine. In 1935, Dakin and West⁷ prepared the principle in such form that 80 mg parenterally was effective in producing a remission in pernicious anemia patients. They considered the active principle to be a complex consisting of an aminohehexose or glucosamine and certain amino-acids. Pyrimidine and purine bases were absent according to them. In the same year,

* Presented at the St. Louis meeting of the American College of Physicians, April 22, 1937.

From the Department of Physiology and Pharmacology, University of Louisville School of Medicine.

Fiske and his coworkers⁸ reported that the hemopoietic principle was probably a combination of L-tyrosine, a complex purine, and a third unidentified fraction. In 1936, Dakin and his collaborators⁹ modified their previous conception somewhat and reported that the principle was a peptide containing arginine, leucine, glycine, proline, hydroxy-proline, aspartic acid, and an acid resembling hydroxy-glutamic acid. In the same year, Wilkinson¹⁰ reported the preparation of the principle in such form that 18 mg. was sufficient to produce a remission in pernicious anemia and Strandell, Laland and their coworkers^{11, 12} stated that they had a product which was effective in the astoundingly small dose of 0.7 mg. Neither of these groups of investigators gave any data on their conceptions of the chemical structure of the hemopoietic principle. The chemistry of the principle, therefore, is still unsettled, although as indicated, there has been considerable progress. Very little is known about the chemistry of the two precursors of the hemopoietic principle. The intrinsic factor of the gastric juice is probably enzymic in nature, it is heat-labile, and otherwise different from the liver principle.¹³ The so-called extrinsic factor of the dietary likewise has not been identified chemically as yet but it is known to be relatively heat-stable and to be associated with protein, especially that of beef muscle, autolyzed yeast eggs, rice polishings, wheat germ, and liver.¹⁴ Although it was once thought that the extrinsic factor was vitamin B₁₂ (G), this is now definitely known not to be the case.^{15, 16}

Since the hematogenic liver principle cannot be tested for chemically, preparations thought to contain it must be assayed biologically. Up to the present, the only satisfactory assay subject is the untreated pernicious anemia patient showing a red blood cell count of 3,000,000 or less.¹⁷ After a control period of 1 to 7 days, the material to be tested is administered during a 10-day interval and daily reticulocyte counts together with erythrocyte, hemoglobin and leukocyte determinations every two to three days are made. The presence of satisfactory quantities of the hemopoietic liver principle in the preparation assayed is shown by a temporary reticulocytosis reaching its peak on the fifth to the eighth day and an accompanying or succeeding increase in erythrocytes and hemoglobin. The minimum reticulocyte response to be expected with a potent preparation is to a certain extent inversely proportional to the original level of the red blood cells. The standard minimum reticulocyte responses are as follows: for a level of 1,000,000 red blood cells per cu. mm., 30 per cent, 1,500,000, 18 per cent, 2,000,000, 12 per cent, 2,500,000, 7 per cent, and 3,000,000, 4 per cent. However, during the past few years, the use of this method of clinical assay has become increasingly difficult owing to the scarcity of untreated patients with pernicious anemia. Moreover, work on the chemistry and physiology of the hemopoietic principle and on the pathogenesis of pernicious anemia and other macrocytic, hyperchromic anemias has been greatly impeded. Hence numerous attempts have been made to devise a suitable laboratory method of bioassay. Of the many procedures proposed, the so-called guinea

pig,^{18, 19} rat,²⁰ and pigeon²¹ methods have received most attention. Each of these depends upon the production of a significant reticulocytosis in normal members of these species by the administration of material containing the hemopoietic liver principle. The validity of each of these methods has been questioned especially on the ground that the reticulocytoses regarded as significant are actually within the limits of normal variability. Certainly the magnitude of the reticulocyte increases regarded as significant by the proponents of the guinea pig and rat methods are very small. Recently we have modified the original pigeon method in such a way as to overcome the objections which have been raised against it.²² Unfortunately, however, we have found that the reticulocytosis produced in pigeons by the hemopoietic liver principle is not specific for this substance. This same objection of non-specificity applies equally forcibly to the guinea pig and rat methods. Our modification of the pigeon method, however, is of definite value as a negative test and further work with liver preparations of known effectiveness or ineffectiveness in pernicious anemia may well show it to be of value in a positive way as well. The ideal laboratory bioassay procedure, of course, involves the production of experimental pernicious anemia, or at least a readily obtainable, chronic, and reasonably severe macrocytic, hyperchromic anemia in animals. Although I shall speak later of experimental macrocytic, hyperchromic anemias produced in animals, difficulties of a practical or other nature appear to preclude the utilization of any of those produced thus far for assay purposes.

Having considered the chemistry and bioassay of the hemopoietic liver principle, we now pass to a consideration of certain facts known concerning its physiology and pathological physiology. Subsequent to the demonstration by Minot and Murphy of the effectiveness of liver in the treatment of pernicious anemia, Castle and his coworkers²³ in 1928 showed that whereas normal human gastric juice mixed with beef muscle was, like liver, effective in the treatment of pernicious anemia when administered orally, a mixture of beef muscle and gastric juice from patients with pernicious anemia was ineffective. Despite some contradictory findings, subsequent work by others has amply confirmed Castle's conclusion that by the interaction of the so-called intrinsic factor of the gastric juice and the so-called extrinsic factor of the dietary, there is formed in the upper gastrointestinal tract of the normal individual a third substance which is absorbed by way of the portal circulation and stored in the liver. From there, probably after further elaboration, the hemopoietic principle is released by way of the blood and passes to the bone marrow to exercise its characteristic effect in facilitating the maturation of the red blood cells from the megaloblastic to the normoblastic stage. Due to the comparative absence of the intrinsic factor in the gastric juice in pernicious anemia, the physiologic process just outlined is grossly deficient and as a consequence normal hematopoiesis is depressed with the resulting macrocytic, hyperchromic anemia, granulopenia, and thrombopenia characteristic of this disease. Whereas normal hog dog

beef, and human livers have been shown to contain appreciable quantities of the hemopoietic principle, the livers of untreated or inadequately treated pernicious anemia patients have been found to be devoid or nearly so of this substance^{24, 25}. Obviously, if the physiological cycle outlined for the hemopoietic liver principle is correct, interference with its normal sequence in other ways should result in a macrocytic, hyperchromic type of anemia. (1) Thus one might expect that gastrectomy would lead to a pernicious anemia-like blood-picture. However, complete gastric resection in the rat,²⁶ hog,^{27, 28} dog,²⁹ and monkey³⁰ has led only to a mild microcytic, hypochromic anemia in the hands of all investigators except one,³¹ although the amount of the hemopoietic principle in the liver of the hog has been shown to decrease following gastrectomy.^{7, 12} The explanation of these essentially negative results is not entirely clear but the fact that the intrinsic and extrinsic factors have been shown to be present not only in the wall of the stomach but also in the wall of the duodenum^{32, 33} and probably the jejunum, ileum,³⁴ and colon of the hog may well be important in this connection. On the other hand, a macrocytic, hyperchromic anemia resembling that of pernicious anemia develops in a definite percentage of humans subjected to complete gastrectomy for carcinoma or other causes and is relieved by the administration of the hemopoietic liver principle.³⁵ (2) A lack of the extrinsic factor in the diet should result in a deficiency of the hemopoietic liver principle. Thus far the difficult task of devising a diet free of the extrinsic factor and feeding it to animals has not been reported. However, a vitamin B₁₂ deficient diet which was probably also deficient in the extrinsic factor, has been shown to produce a macrocytic anemia in approximately half of the hogs to which the diet was given. Moreover, the intrinsic factor was reported to have disappeared from the gastric juice of the anemic animals.³⁷ A macrocytic anemia in monkeys on a vitamin B₁₂ deficient diet, probably lacking in the extrinsic factor, has also been reported.³⁸ Clinically a dietary lacking in the extrinsic factor appears to be one of the factors involved in the genesis of the macrocytic anemia which may occur in sprue.³⁹ It is likely also that a deficient intake of the extrinsic factor is responsible for tropical macrocytic anemia, in which treatment with either the extrinsic factor or the hemopoietic liver principle is effective.⁴⁰ (3) Deficient absorption of the product of the interaction of the intrinsic and extrinsic factors should also produce a blood-picture resembling pernicious anemia. Experimentally, a macrocytic, hyperchromic anemia has been produced in dogs by stricturing the small intestine and thus, according to one interpretation, producing changes in the intestinal wall which interfere with the absorption of the hemopoietic principle.⁴¹ Clinically, macrocytic anemia may appear in sprue, ileitis,⁴² and patients with intestinal strictures⁴³ or gastro-colic fistulae⁴⁴ where the absorption of the hemopoietic substance is undoubtedly interfered with, and in such patients parenteral therapy with the hemopoietic principle is of value in removing the anemia. (4) Sufficiently severe damage to the liver with resulting inade-

quate storage and elaboration of the hemopoietic principle should also produce a pernicious anemia-like blood-picture, if the physiological cycle outlined for the hemopoietic principle is correct. Experimentally, the repeated administration of large doses of carbon tetrachloride to dogs and rats with a consequent severe chronic liver damage and cirrhosis has led to the appearance of a macrocytic, hyperchromic anemia in some of the animals⁴⁵. The same result was obtained in a few dogs by gastrectomy followed by carbon tetrachloride administration⁴⁶. Clinically, there are many reports of macrocytic, hyperchromic anemia occurring in patients with cirrhosis of the liver^{47, 48, 49} and very probably some degree of macrocytosis occurs in nearly all patients with advanced diffuse liver disease^{50, 51}. Moreover, assay of the livers of patients with cirrhosis and a pernicious blood-picture has shown such livers to be deficient in the hemopoietic principle and the administration of the principle is effective in relieving the anemia in some of these patients.

We shall now consider data on two other points relative to the physiology of the hemopoietic principle. These involve its storage in sites other than the liver and its excretion. (1) Thus far the liver is the only proved site of detectable quantities of the hemopoietic principle. Dried, defatted hog stomach, duodenum, and probably jejunum, ileum, and colon are effective in the treatment of pernicious anemia when administered orally not because they contain the hemopoietic liver principle but because they contain its two precursors, the intrinsic and extrinsic factors. Salivary glands⁹ and muscle do not contain the liver principle. Neither do saliva,⁵² gastric juice,⁵³ or duodenal juice,⁵² although some workers have claimed that gastric juice does^{54, 55}. Kidney,⁵⁶ brain,⁵⁷ and pancreas have been shown to be effective in pernicious anemia when administered orally. Kidney is as effective as whole liver by mouth, whereas brain and pancreas are approximately one-third as effective. What the active materials in these organs are and what relation they have to the hemopoietic liver principle are not completely apparent at present. In the case of the kidney and brain, however, Dakin, Ungley, and West⁹ have presented strong evidence that the potent substance is not the hemopoietic liver principle, inasmuch as extracts of kidney and brain prepared by methods yielding potent parenteral liver extracts were ineffective parenterally in pernicious anemia. Recently we obtained similar results with kidney⁵⁸. (2) In view of the fact that the hemopoietic liver principle undoubtedly passes to the bone marrow via the blood stream, we examined normal human urine for the possible presence of the substance. First we found normal human urine to be reticulocytogenic for the pigeon similarly to liver extract⁵⁹. Other investigators have reported like findings using the rat⁶⁰ and guinea pig⁶¹. We then prepared an extract of urine by a method basically that employed in making liver extract and found the urinary extract to be reticulocytogenic for the pigeon. In the cruder chemical properties of solubility and relative heat-stability the reticulocytogenic urinary principle resembled the hemopoietic liver principle. However, in view of the non-specificity of the pigeon method of assay, the urinary

extract was then studied in pernicious anemia patients. Negative results in three patients showed definitely that the urine principle is not the hemopoietic liver principle.¹⁰ The hemopoietic principle, therefore, is not excreted as such in detectable quantities in the urine. Just what the relation of the reticulocyteogenic urine principle to the hemopoietic liver principle is cannot be stated at present, although we are inclined to consider the former a decomposition product of the latter.

In this brief discussion I have attempted to summarize for you certain features of our present knowledge of the chemistry, bioassay, physiology, and pathological physiology of the hemopoietic liver principle. As you have gathered, this knowledge in many respects is incomplete. However, as our knowledge of the principle increases, many of the present obscurities in the physiology of hematopoiesis and in the pathogenesis of certain of the blood dyscrasias will be swept away.

THE HEMATOPOIETIC RESPONSE FOLLOWING ORAL ADMINISTRATION OF DESICCATED DUODENAL MUCOSA *

By JOHN C THOMPSON, F A C P , *Lincoln, Nebraska*

THE fundamental work of Castle and his coworkers ^{1, 2, 3, 4} proving that a definite antianemic substance, "Intrinsic Factor," is produced in the wall of the stomach, at present seems to be established beyond a reasonable doubt. The theories developed by the author on the basis of this monumental discovery have, however, been questioned by a number of observers. Some of these objections, notably those of Greenspon,⁵ have had to do with the nature of the antianemic material and the method of its production in the stomach. A more serious discrepancy, however, exists in the theory that this vital material is developed only in the stomach and stored in various other structures of the body. It is the purpose of this paper to offer some facts to prove that this assumption is incorrect and that antianemic material is also produced in other portions of the gastrointestinal tract.

From a clinical point of view the fact that complete or at least extensive gastrectomy does not promptly produce the picture of a primary anemia should at once cast a reasonable doubt on the completeness of Castle's hypothesis. In 1933 Roeder⁶ collected from the literature the clinical records of 88 cases of complete removal of the stomach while Goldhamer⁷ in the same year following a similar search discovered only 23 cases of severe anemia following this operation. In Roeder's report reference was made to a case of A. W. Mayo Robson's living and in apparently good health 30 years following an almost complete gastric resection. Cases reported by Walters,⁸ Judd and Marshall,⁹ Clute and Mason,¹⁰ Morrison,¹¹ and others failed to exhibit any sign of pernicious anemia at intervals varying from several months to years following their operation. Poole and Foster's¹² case lived for three years following a complete gastrectomy without noticeable blood changes, then developed a pernicious anemia which responded well to appropriate treatment. These latter authors expressed the view that in any instance complete removal of the stomach would eventually lead to the development of an Addisonian type of anemia if the patient's post-operative life was sufficiently long.

In his 23 cases Goldhamer found only one individual in whom the anemia appeared as early as the fifth month, in the others it came on at intervals varying from one to 15 years. From this observation he concluded that the time element was an important factor in the development of the condition.

On the experimental side Ivy, Morgan, and Farrell¹³ reported in 1931, after a study extending over a period of seven years, that of 14 gastrectomized dogs, living for six months or longer following operation, three

* Received for publication February 25, 1937

developed a spontaneous anemia, and three were anemic only during pregnancy. The anemia observed was of secondary type and was responsive to treatment by iron. This work was confirmed by Mullen¹³, Dragstedt, and Bradley¹⁴ in 1933, and by Dragstedt, Bradley and Mead¹⁵ in 1935. Maisson and Ivy¹⁶ in 1933 reported similar observations on swine and suggested at this time that an intestinal factor might be the cause of their failure to produce a macrocytic hyperchromic blood picture. Judd and Marshall in their report on gastric resection stated that Mann had three dogs living over four years following gastrectomy, in good health and without anemia.

A study of the cases collected by Goldhamer and others is of especial interest in view of the results of the experimental physiologists, for it is quite apparent that at least some of the clinical records do not contain a sufficient amount of evidence to establish clearly a diagnosis of pernicious anemia and it is quite possible that some of these individuals suffered with the same hypochromic, iron requiring anemia which proved fatal in some of the experimental animals. It is further to be noted that a number of the dogs operated upon experimentally lived for years without developing a primary anemia. This would add some color to the views expressed by Poole, Foster and Goldhamer to the effect that time is an essential element in the development of the condition. While this premise is doubtless true then implied explanation cannot be accepted, for it is illogical to assume that the vital antianemic material is produced only in the stomach, and stored in the liver or other tissues in such inexhaustible quantities that its presence in effective amounts would be felt for months or even years after its source of renewed supply was completely abolished.

Further study of gastric secretion has also brought to light certain facts not adequately explained by Castle's postulates. This author in his investigation of two individuals suffering with typical Addisonian anemia but with apparently normal gastric juice found that the intrinsic factor was absent. In one individual with complete achylia but without anemia and in three persons suffering with anacidity and hypochromic anemia he found the material present. On the contrary Barnett¹⁷ in 1931 reported two cases, one of spure, and the other with a typical pernicious anemia, both of whom had normal gastric secretions containing a sufficient amount of intrinsic factor to produce a remission in an untreated case of the latter disease. In 1932 Barnett¹⁸ published a report concerning several cases of anacidity in which the intrinsic factor was missing but the individuals exhibited no signs of anemia. In 1935 Goldhamer, Isaacs, and Sturgis¹⁹ found that the gastric secretion of untreated cases of pernicious anemia contained appreciable quantities of intrinsic factor. They were able to demonstrate a definite relationship between the volume of gastric juice found in the stomach and the erythrocyte level in the usual case suffering with the disease. They also discovered that the average volume of gastric secretion was 20 c.c. per hour in the anemic individuals whereas normal persons produced 150 c.c. per hour. Their work would imply that a re-

duction in volume of gastric secretion would necessarily reduce the available supply of intrinsic gastric factor. Yet, Bloomfield and Pollard²⁰ found after a study of 45 cases of anacidity, extending over a period of one to seven years that not one of these individuals had developed a pernicious anemia. This group included two of the cases previously reported by Barnett in 1932 in whom the intrinsic factor was absent. At present these separate facts taken from the literature might be considered to be controversial in character and in the light of Greenspon's recent observations it is possible that failure to take into account peptic activity may have influenced the results obtained by various observers. There is suggested, however, from these experiments a possibility that intrinsic factor may be derived from other sources than the stomach. If the latter assumption is true then the cases first reported by Barnett were anemic because the unknown source of intrinsic factor was exhausted and the gastric supply was insufficient to handle the situation. In the cases of anacidity later reported by Barnett, Bloomfield, and Pollard anemia did not occur in the absence of intrinsic gastric factor for the reason that the unknown source adequately met the requirement for blood regeneration. The observations of Goldhamer, Isaacs, and Sturgis would suggest that if in the ordinary case of pernicious anemia the erythrocyte level paralleled the volume secretion of the stomach that in such usual cases the output of the second unknown source of supply must necessarily rise and fall with the volume production of the stomach. This would not only imply that the development of intrinsic factor is a quantitative reaction but would suggest some close physical relationship between the stomach and this as yet unrecognized source.

The idea that the gastrointestinal tract might provide a source of intrinsic factor production other than the stomach was discouraged by the original contribution of Castle who reported that this material was not demonstrable in normal human saliva or duodenal contents free from gastric juice. On the contrary Maisson and Ivy in their work on swine suggested that an intestinal factor might enter into their failure to produce the hyperchromic blood picture. From the pathological view point Brown²¹ in a discussion of the pathology of pernicious anemia pointed out the frequent occurrence of lesions in the small intestine while the literature on the subject of tropical and non-tropical sprue has contained frequent reference to the presence of intestinal pathologic alterations.

From a clinical and experimental aspect the literature is not devoid of material suggesting the possibility of an intestinal factor in the production of hyperchromic anemia. In 1927 Seydelhelm, Lehman, and Weichels²² reported that a pernicious anemia-like blood picture occurred in dogs after experimental stricture of the small intestine. In 1929 Little, Zervas, and Fressler²³ reported a clinical instance of pernicious anemia following lateral anastomosis and chronic small intestinal obstruction in man. During the same year Meulengracht²⁴ found 21 similar cases in the literature and reported another. In 1936 Hawksley and Meulengracht²⁵ reported still

another case and found that a total of 24 had made their way into the literature up to that time

At present Castle's postulate, to the effect that a lack of intestinal absorption of potent anti-anemic material is responsible for the development of certain cases of primary anemia, has been accepted as an explanation for the development of hyperchromic anemia in the above mentioned cases of intestinal stricture as well as in cases of idiopathic steatorrhea and sprue. It is, however, just as reasonable to assume that the blood picture in these conditions is due either partially or completely to a failure of the small intestine to produce in adequate amounts its share of the required intrinsic factor. If the latter assumption is correct then the frequent incidence of anacidity and disturbed gastric secretion in cases such as those cited above has a real significance for we must conclude then that primary anemia is essentially a condition produced by a definite quantitative loss of intrinsic factor production in both the stomach and intestine. Such a conclusion provides a more reasonable explanation for the results of experimental and clinical gastrectomy, for if the appearance of primary anemia is the result of the loss of a definite quantity of intrinsic factor produced in both the stomach and bowel the delayed development of this anemia must be due to gradually developing pathological changes in the intestinal mucosa and a destruction of its capacity to produce antianemic material. In this connection it must be emphasized that Castle's hypothesis assuming that all precursor substance arises in the stomach excludes any question of intestinal absorption in the cases of total gastrectomy for the reason that with intrinsic factor absent there should be nothing to absorb.

With this theoretical background it yet remains to offer some substantial proof that intrinsic factor can be and is developed in the intestinal tract. As was previously stated, Castle in 1928 found that antianemic activation of meat did not occur with duodenal section. In 1933 Kuehnau²⁶ carried out a number of feeding experiments which suggested that intrinsic factor was present in the duodenal juices. His work, however, was open to criticism for he employed a mixture of duodenal and gastric secretions. In 1935 Meulengracht²⁷ reported positive results in the treatment of primary anemia with duodenal mucosa, while Cheney²⁸ in 1936 discovered that liver extract incubated with duodenal mucosa produced an anti-anemic material of potency equal to or greater than that of the commercial product "Extralain" developed in similar fashion by the incubation of liver with stomach mucosa.

The present work was undertaken in January 1935 and has been carried on continuously for a period of two years. During this interval a number of individuals suffering with pernicious anemia in relapse and various other anemic states have been given a preparation of desiccated duodenal mucosa with results which indicate the presence of a potent anti-anemic substance in the duodenum. The material used in this experimental work has been generously provided by the Research Division of the Eli Lilly Co., and has

been prepared by the usual methods of desiccation from the duodenal mucosa of swine. Each gram of the finished product has represented 4.5 grams of raw substance.

CASE REPORTS

Case 1 *Pernicious anemia in relapse*

History The patient, Geo C L, aged 66, carpenter, was seen on July 19, 1935, complaining of anemia, weakness, dyspnea on exertion, dull aching in the chest, palpitation of the heart, swelling of the feet and ankles, numbness and tingling in the hands and feet, dull aching in the limbs after a short walk, abdominal distress, slow stream and dribbling of urine. Some of these symptoms dated back to 1921 when a diagnosis of pernicious anemia had been made. During that year the anemia had been so severe that transfusion was done. Occasional relapses then occurred requiring transfusion until the advent of the liver diet.

FIG 1

In July 1929 an office record indicates that he had been unable to work for a period of seven months because of weakness, numbness in the lower extremities, etc. Salient points of the examination at the time were: A lemon yellow pallor of the skin, red blood cells 2.62 millions, a systolic murmur at the cardiac apex, normal heart boundaries, blood pressure 120 mm of Hg systolic and 60 diastolic, liver edge just below the costal margin and a palpable spleen. Complete remission then occurred on Lilly's Liver Ext 343 in a dose of two vials three times daily. During the following years owing to financial difficulties the patient was able to maintain adequate treatment only at intervals and in consequence his erythrocyte level was subject to wide variations. On August 8, 1930, the red blood cells were 1.60 millions and the hemoglobin 35 per cent while on February 21, 1933, the red blood cells were 4.84

millions and the hemoglobin 82 per cent. Response to proper therapy during this interval, however, was always satisfactory. From February 21, 1933 on, a physician was not consulted until he presented himself for treatment on July 19, 1935 with the symptoms outlined above, most of which had been present for a considerable period of time.

Physical Examination. The patient was a moderately thin white male. Pulse 72. Temperature 98.6° F. Pupillary reactions were normal. Pyorrhea and recession of the gingivae were noted about the remaining teeth. The tongue was slightly coated but the papillae were still present and there was no evidence of glossitis. Mucous membranes were pale. The radial arteries were thickened. The heart was slightly wide at the base. The heart sounds were somewhat muffled, a roughness of the first sound was heard in the aortic area, and a systolic murmur, not transmitted, was present at the apex. The lungs were emphysematous and subcrepitant râles were heard on inspiration particularly over the bases. The liver edge was three fingers-breadth below the costal margin. The spleen was not palpable. The feet were cold and clammy and pulsation in the dorsalis pedis arteries could not be definitely palpated. Vibratory sense was somewhat questionable. Neurological examination otherwise was negative. The prostate was atrophic, its secretion contained considerable pus. Dorsal kyphosis with moderate limitation in movements of the spine was noted.

Laboratory Examinations. Upon roentgen-ray investigation the thoracic aorta was found to be slightly dilated and its shadow increased in density. The excursion of the diaphragm was limited and some infiltration was noted along the lower bronchi. The gastrointestinal tract was negative except for moderate ptosis.

The hemoglobin was 48 per cent (Sahli). The red blood cell count was 1.45 million. Volume index was 1.2. Reticulocytes were absent. Poikilocytosis and anisocytosis were noted as well as a very definite macrocytosis. The white blood cell count was 9,700 and upon differential count there were 40 per cent lymphocytes, 3 per cent monocytes, 4 per cent juvenile forms, 10 per cent rod forms and 51 per cent segmented cells. Of the latter, 34 per cent contained three or more divisions of the nucleus. The blood Wassermann test was negative. The stomach contents contained no free acid after histamine. Blood calcium was 9.5 mg. and phosphorus 3.2 mg. per 100 cc. of blood. The bromsulphalein liver function test, at 5 minutes, showed 40 per cent retention of dye, at 15 minutes 25 per cent, and at 30 minutes none. Urine was negative.

Treatment and Progress. On July 19, 1935, the patient was placed on 15 gm. of desiccated duodenal mucosa, representing 72 gm. of raw material daily. This treatment was continued without interruption and with no other medication until September 11, 1935, a total of 54 days. The reticulocyte count increased from zero to a peak level of 14.8 per cent on the eighth day. The erythrocyte count changed from 1.45 million on July 19 to 3.9 million on September 3, a total of 46 days, and an average gain of 375,000 cells per week. Hemoglobin rose from a low point of 40 per cent to 78 per cent on September 3. Because of slight edema of the feet and ankles, a slight dyspnea on exertion, and some enlargement of the liver the patient was given digitalis in a dose of 4½ grs. of powdered leaf daily beginning September 11. This treatment has been continued at intervals. On October 23, 1935, a moderate dose of iron was prescribed. In December 1935 an investigation of the bladder for residual urine was negative. During the early months of 1936 the patient had an acute respiratory infection and some trouble with hemorrhoids requiring treatment. On March 30, 1936, the red blood cells were 4 million and hemoglobin 90 per cent. During the months of April, May, and most of June the patient did not return for observation and received no treatment. On June 27, 1936, the red blood cell count had dropped to 2.9 million and the hemoglobin to 64 per cent. On December 9, 1936, on treatment the red blood cell count was 4.4 million and the hemoglobin 87 per cent.

The total period of observation in this case has been 18 months. During this interval the erythrocyte count has been maintained at a satisfactory level on relatively small amounts of desiccated duodenal mucosa and has dropped very definitely on one occasion when the patient failed to take this material over a considerable period of time. General health has been very much improved although some symptoms due to arteriosclerosis persist and are troublesome.

Case 2 *Pernicious anemia in relapse*

History The patient, Mrs. M. H., aged 47, was first seen on April 1, 1936. The major complaints at the time consisted of a feeling of fatigue and weakness, and a numbness in the hands and feet. The latter symptom was so severe that the patient lacked definite control of her extremities. She could not walk in the dark without assistance, and she frequently dropped dishes and other objects from her hands. She had experienced a soreness of her tongue at its tip and edges at intervals for three years. She suffered with anorexia, nausea, salivation, flatulence and constipation. She complained of a low backache, nervousness, and leukorrhea. The development of these symptoms had occurred over a period of months to years. The menopause had occurred three years previously. History in all other respects was essentially negative.

FIG 2

Physical Findings Upon physical examination temperature was 99.5° F, pulse 76, and weight 10 pounds over optimum normal. The skin had a distinctly lemon yellow color. The mucous membranes were pale, and the sclerae pearly white. The tonsils were chronically inflamed. Considerable pyorrhea and gum recession were noted. The papillae of the tongue were not atrophic but patchy reddened areas

occurred along its edges. A cystic type of goiter was present of moderate size. The heart and lungs were negative. Blood pressure was 108 systolic and 74 diastolic. The abdomen was negative except for the presence of a spastic palpable sigmoid and moderate tenderness in both lower quadrants. Pelvic examination was negative. The knee jerks were sluggish. Plantar reflexes were normal. Epicritic sensibility was diminished and vibratory sense was absent. Romberg's sign was questionable. Hypertrophic changes were noted in the terminal interphalangeal joints.

Laboratory Data The laboratory data were as follows: Erythrocytes 2.5 million, hemoglobin (Sahli) 65 per cent, Volume index 1.2, Color index 1.3, White blood cells 3700. A definite macrocytosis was present with anisocytosis and poikilocytosis. The differential count was lymphocytes 64 per cent, monocytes 2 per cent, stab forms 10 per cent, segmented cells 24 per cent. No free acid was present in the stomach contents after histamine. The stool contained no blood, ova, or parasites. The blood Wassermann was negative. Blood calcium was 11.5 mg per cent. Basal metabolic rate was plus 11. Urine was negative.

Treatment and Progress A diagnosis of pernicious anemia was made and treatment was started on April 4, 1936. The patient was given desiccated duodenal mucosa in a dose of 15 gm daily from April 4 to April 24. During this interval a gain of 940,000 cells occurred or an average weekly increase of 329,000. On April 24 the dose was increased to 30 gm daily for a few days followed by a daily administration of 15 gm daily until June 15. The blood picture had returned to practically a normal condition on May 18, a total of 44 days. On June 15 the dose was reduced to 10 gm daily. The average quantity consumed daily between the dates of July 6 to September 23, 1936, was 9 gm. No other therapy was advised with the exception of rest during the early phases of treatment and dental therapy which was started on May 28.

Upon the date when treatment was instituted the patient was hardly able to be up and about. Gastrointestinal complaints had disappeared by April 24 and the blood counts had returned to normal by May 28. The patient at this time was doing all of her own work. By July 21 she had very little complaint with reference to paresthesias and was scrubbing, washing, ironing and doing a large amount of hard work each day. The patient was last seen on January 18, 1937, at which time in spite of rather small dosage her erythrocytes were 4.4 million and hemoglobin 97 per cent. She had no complaints at this time.

Case 3 Pernicious anemia in relapse

History The patient, Mrs. W. C., aged 81, entered the Lincoln General Hospital on March 19, 1936, complaining of nocturia, diurnal frequency, and pain in the upper right quadrant. These symptoms had confined the patient to her bed for two weeks. In addition she had suffered with weakness and fatigue for six months, anorexia for four months, numbness in the hands for four months, slight dyspnea for years, and moderate edema of the feet and ankles. Coincident with urinary symptoms the patient had also suffered with pain and distress in the right flank and right upper abdomen.

Examination The patient was well nourished. Temperature 98° F, pulse 84. The skin had a definite lemon yellow color and the sclerae were pearly white. The tongue was smooth and areas of redness were found along the edges. The heart boundaries were normal. The peripheral arteries were not sclerosed. A systolic murmur was heard at the cardiac apex. A rather marked tenderness and rigidity were noted in the upper right quadrant and right flank. Vaginal examination was negative. A slight pitting edema was noted in the ankles. The knee jerks were sluggish. Vibratory sense was lost in the lower extremities. Plantar reflexes were normal.

Laboratory Data The urine on March 19, 1936, contained considerable pus. The erythrocytes were 1.36 million and the hemoglobin was 38 per cent (Sahli). Volume index was 1.4. Reticulocyte estimation was 0.8 per cent. Macrocytosis, anisocytosis,

poikilocytosis, and polychromatophilia were present. The differential was lymphocytes 50 per cent, monocytes 25 per cent, metamyelocytes 15 per cent, eosinophiles 1 per cent, basophiles 05 per cent, segmented forms 44 per cent, stab forms 05 per cent. On March 21, the stomach contents contained no free acid. On March 24, a urine culture was positive for *Escherichia coli*. Intravenous pyelogram done on April 7 showed a normal kidney function with normal pelvis and ureters.

Treatment and Progress. Thirty grams of desiccated duodenal mucosa were given daily beginning on March 20, 1936, and continuing until the patient left the hospital on April 12. During this interval the erythrocytes increased from 136 million on March 19, 1936, to 159 million in four days, to 168 million in seven days, to 197 million in 13 days and 245 million in 20 days. Reticulocytes multiplied from 08 per cent on March 19 to 96 per cent 10 days later. Daily counts were not made and the

FIG 3

peak probably occurred prior to this day. Hemoglobin increased from 38 per cent to 56 per cent on April 9. A diagnosis of a right infected hydronephrosis was made which was thought in turn to be possibly due to a cord bladder. Treatment for this condition consisted of bed rest, urinary antiseptics, nitrohydrochloric acid, bladder catheterization and lavage. The infection cleared up promptly.

On the twenty-third day the patient was discharged from the hospital in very good condition with a supply of desiccated mucosa and a request to report at frequent intervals. Instructions were given to take 15 gm of the material daily but the dose was reduced and the patient did not return until May 6. On this, her forty-seventh day of treatment, the erythrocytes were 44 million and the hemoglobin was 74 per cent. The increase of red blood cells for the 47 day period amounted to 305 million or an average per week of 450,000 cells. At this time the patient was not only doing some housework but was also spending some time in her garden.

In spite of a warning the patient continued to be careless in her attitude toward the use of antianemic material. Between the dates of June 19 and September 11, she

consumed a total of 540 gm on a daily average of 6 gm. After September 11 she had no treatment until she finally returned on November 20, 1936. At this time she had no particular complaints. She had suffered with no recurrent abdominal distress or urinary symptoms and her urine contained no pus. Her erythrocytes, however, had fallen to 2.9 million and the hemoglobin was 70 per cent. She was again given 30 gm daily and nine days later the erythrocytes were 3.57 million and the hemoglobin 78 per cent. Subsequent changes in the erythrocyte count are unknown for the patient left the city for the winter.

Case 4 Pernicious anemia with combined sclerosis of the spinal cord

History The patient, Mrs. F. W. J., aged 64, housewife, first presented herself for examination on January 24, 1935, with the outstanding symptom of abdominal distress. She stated that this trouble had been present for years and was accompanied by a severe constipation requiring constant catharsis, flatulence usually aggravated by cabbage, raw apples, etc., occasional passage of light colored stools, and pain of moderate severity usually felt in the lower abdomen but occasionally experienced above. She had been troubled with hemorrhoids, and bright red blood had appeared in her stools frequently over a period of 20 years. In addition she complained of weakness, nervousness, a numbness in the lower extremities present for the preceding five months, and a frequent soreness of the mouth which she described as canker sores. The latter had occurred over a period of at least four years. For years she had also been troubled by a loss of the sense of smell. This symptom had developed after a severe head cold. In other respects the history was essentially negative.

Physical Examination The patient was 35 pounds under her normal weight. Temperature was 98° F, pulse 84. The examination of the head and neck was negative, excepting for the presence of several questionable teeth. Blood pressure was 164 systolic, and 96 diastolic. Peripheral vessels were normal. The heart was of normal size but a slight roughness of the first and a reduplication of the second tone were heard at the apex. The lungs were negative. A tenderness and a sense of resistance were noted in the upper right quadrant and the sigmoid was tender, spastic and palpable. The liver edge was slightly below the costal margin. The spleen was not palpated. Vaginal examination was negative. Upon inspection a number of inflamed hemorrhoids were noted. The knee jerks were sluggish. Circulation in the lower extremities was normal.

Laboratory Data (First admission) A non-functioning gall-bladder with gastroparesis, cecal stasis, and a slowing of the gradient through the large intestine was found on roentgen-ray examination. No free acid was present in the stomach contents either before or after histamine. The urine was negative. Icterus index was 10. Blood calcium was 8 mg and phosphorus 3.2 mg per 100 cc of blood. Hemoglobin was 85 per cent. Red blood cells were 3,880,000, and white blood cells 4700. Upon differential count the cells were classified as follows: Lymphocytes 60 per cent, monocytes 2 per cent, juvenile forms 6 per cent, stab forms 6 per cent, and segmented cells 26 per cent. Volume index was not done. A slight poikilocytosis was noted. Blood Wassermann test was negative. The stool contained neither parasites nor blood but was thin as a result of catharsis.

Initial Treatment Following this examination the patient was admitted to the Bryan Memorial Hospital and operated on February 18, 1935. The gall-bladder was found to be thick-walled, gray, and adherent to the duodenum. The appendix was retrocecal and adherent to the terminal ileum. Both were removed as well as three large, protruding internal hemorrhoids. The patient was discharged from the hospital on March 3, 1935, with no complaints and her strength rapidly improving.

History and Examination (Second hospital admission) The patient reentered the hospital on May 23, 1935, with the statement that for one month after being discharged on March 3 she had noted a very definite improvement in strength and felt no paresthesias. At the end of this time, however, there gradually developed

a marked numbness with peculiar sensations of burning, and tingling in the hands and limbs, difficulty in walking, weakness, and an abdominal distress arising chiefly from constipation

Upon examination the patient was undernourished, and unable to support her weight on her limbs. The tongue was very smooth. The abdomen was distended and the wall was thin. The knee jerks and tendo-achilles jerks were absent. The plantar reflexes were very sluggish. Both epicritic and vibratory senses were absent. Muscle strength in the limbs was fair but the patient was unable to stand or walk because of ataxia of the lower limbs. Finer movements of fingers and hands were also affected. Muscle sense in the limbs was impaired. On May 27 the erythrocyte count was 3.2 million and the hemoglobin 80 per cent. No reticulocytes were present. Volume index was 1.18. White blood cells, 5000. Poikilocytosis and anisocytosis were noted. Differential count was: Neutrophile rods 3 per cent, segmented cells 49 per cent, lymphocytes 46 per cent, and monocytes 2 per cent.

Treatment and Progress. On May 26 the patient was started on desiccated duodenal mucosa in a daily dose of 25 gm. After 17 days this dose was reduced to 20 gm daily and continued for 17 days. At the end of 34 days the patient was tried at intervals on liver extract intramuscularly, extralin and later ventriculin. On each occasion, however, after a few days a definite loss of strength and an increase of symptoms were noted. A maintenance dose of 10 gm of duodenal mucosa was started at the end of 60 days and has been continued with a few interruptions until the present time.

A definite improvement in symptoms was recognized as early as 12 days after the beginning of treatment. At the end of 32 days the patient was able to walk about her home and in her garden with the assistance of a cane. At the end of six months very little or no trace of the former ataxia could be noted. Knee jerks were sluggish but present. Epicritic sensibility had returned but vibratory sense was very

uncertain or absent. A very definite relief from digestive disturbances particularly constipation was also observed on duodenal mucosa while the latter symptom was troublesome while taking ventriculin or liver.

On June 28, 1935 thirty-four days after treatment was started, the erythrocytes were 488 million and the hemoglobin 92 per cent. Since this time normal erythrocyte and hemoglobin levels have been obtained with the exception of moderate decreases occurring especially when treatment with other antianemic substances was utilized in probably inadequate dosage. A definite reticulocyte response occurred with a peak level of 59 per cent at the end of 10 days of treatment on desiccated duodenal mucosa.

Between the dates June 4 and October 2 a total of 120 days the patient was given a daily ration of approximately 12 gm daily. During this interval she maintained a normal erythrocyte count. During the following four months the patient's supply was curtailed and she was advised to use other anti-anemic substances. Whenever a supply was given to the patient during this interval she was required to appear for observation. This entailed a 70 mile auto trip which the patient on all occasions was eager to make for the reason that subjectively she repeatedly noted that she felt better and was stronger when taking desiccated duodenal mucosa.

FIG 5

Case 5 Pernicious anemia with combined sclerosis of cord

History The patient M+ G, aged 53, store clerk by occupation, was first examined on January 14, 1937. He came in complaining of a stiffness in his legs and a feeling of tightness and pressure in the abdomen which he stated had been gradually developing over a period of months. He further complained of a wooden sensation in his hands and feet, a difficulty in walking in the dark, a sexual impotence of 6 to 7 months' standing, a lack of strength, constipation, flatulence, and abdominal distress. He had been unable to work for a period of six months. Past history was negative with the exception of a history of albuminuria 10 years previously.

Examination: Upon physical examination the weight was normal (178 pounds) Temperature was 99.2° F pulse 64. A definite pallor was present. Sclerae were pearly white. The edges of the tongue were bald. The cardiovascular system was negative. Blood pressure was 140 systolic and 76 diastolic. The liver and spleen were not palpable. The abdomen was slightly tympanitic but otherwise negative. The testicles were atrophic. Neurological investigation revealed the presence of a positive Romberg, normal pupillary reactions, exaggerated knee jerks, and tendo-achilles jerks with normal plantar reflexes. Muscle sense was disturbed and a moderate loss of epicritic sensibility was noted in the lower limbs.

Laboratory Data: The laboratory data were as follows: Erythrocytes 2.2 million hemoglobin (Sahli) 70 per cent, white blood cells 5500. Reticulocytes were absent. Anisocytosis, poikilocytosis, and macrocytosis were present. Volume index was 1.1+. Differential count: Lymphocytes 28 per cent, stab forms 12 per cent, segmented neutrophils 58 per cent, juvenile forms 2 per cent. No free acid was present in the stomach after histamine. Blood Wassermann was negative.

Treatment and Progress: On January 15, 1937, the patient was started on 30 gm of desiccated duodenal mucosa daily. This dose was increased to 45 gm daily on January 26, and with one interruption was continued until February 5, a total of 20 days. During this interval the red blood cells increased to 4 million, an average weekly increase of 600,000 cells. The reticulocyte count was probably not taken at its peak but was found at 7 per cent on the ninth day. During this interval the patient was not permitted to walk, but strength and color improved. Constipation was relieved as well as abdominal distress. Neurological changes in the lower extremities remained unchanged.

The red blood count on March 11, 1937, was 5,190,000, hemoglobin was 110 per cent and since this time the hemoglobin has never been below 100 per cent and the red count never less than 5,000,000 up to the present, June 23, 1937. Further, the patient is now able to walk without support of any kind for a considerable distance without tiring. There remains only a very slight feeling of stiffness in the limbs.

Case 6 Non-tropical sprue

History: The patient, Mrs. C. P., aged 32, was first seen on April 24, 1934, complaining of diarrhea, gas, belching, bloating, cramping and abdominal distress, sore mouth and tongue, nervousness, fatigue, and heart burn.

She stated that her illness really started very insidiously while she was engaged in training for the vocation of nursing between the years of 1924 and 1927. During this interval her diet was extremely poor in general quality, contained very little meat, and consisted principally of starchy foods. The dietary habit so established was continued after graduation to a considerable degree and particularly so after a diagnosis of peptic ulcer was made in 1929.

Approximately five years previously the patient had rather suddenly developed a diarrhea associated with fever, and distress in the upper abdomen. She was suspected of having tuberculosis and was placed in bed for a period of six weeks. Fever subsided in six weeks but watery stools continued for six months. Since that time diarrhea had recurred two or three times each year and continued for intervals of six weeks to three months. At the height of this trouble as many as 10 to 12 stools were passed daily. In the intervals movements were normal. During the attacks of diarrhea the patient noticed a marked tendency for movements to occur between 4 and 5 a.m. causing a disturbance of rest and sleep. More trouble had been experienced in summer than during winter months.

Flutulence, bloating and passage of large quantities of gas occurred at the onset and had continued to cause trouble. Rather marked distress was felt in the upper abdomen particularly in the first attacks. Tenesmus and pain accompanied this difficulty. In subsequent attacks these symptoms were not so severe. Heart burn had been present much of the time during the five year interval. Dilute hydrochloric acid

was tried for this trouble but it irritated the mouth and aggravated the symptom. In each attack of diarrhea a swelling of the lips and mucous membranes of the mouth had developed. There were also sores on the tongue which the patient described as not being the usual canker sore. Nausea and vomiting had occurred only at rare intervals and then only when some intercurrent infection was present.

Nervousness had been marked throughout the course of the illness. Limited strength and fatigue were early and persistent symptoms. The patient's strength was not sufficient to permit her to do her usual work and she was required to rest for at least two hours each afternoon. She had noted that fatigue seemed to aggravate her other troubles.

Upon further questioning it was found that the patient had never suffered with numbness, paresthesias, joint pains or muscle cramps. Insomnia had been experienced only to a slight degree.

Menses occurred at irregular intervals varying from 28 to 42 days. The flow was scanty and continued for five days. Pregnancy with death of one twin on delivery had occurred some two years previously. This had been followed by a severe attack of pyelitis. The history in other respects was negative.

Examination (April 24, 1934) The patient's weight was 87½ pounds. Height 60½ inches. Optimum weight 121 pounds. Temperature was 98.8° F, pulse 62. Blood pressure was 112 systolic and 86 diastolic. Patient's color was naturally dark and an undue pigmentation of the face and arms could not be definitely determined. Head and neck were entirely negative except for a few palpable glands in the posterior triangles of the neck. The heart and lungs were negative. The abdomen was distended. The wall was thin, flabby, but symmetrical. Loops of bowel could be noted through the abdominal wall. There was no tenderness or other findings. No edema of the feet and ankles was present. A slight grating was noted in the left shoulder. Vaginal examination was negative. Proctoscopic examination revealed some muscular spasm in the pelvic colon and a slight irritation of the mucosa but no hemorrhoids and no cryptitis.

Laboratory Data Upon radiological examination some calcification was noted in the right hilus with increased lung markings extending downward and outward from this area. The stomach was hyperperistaltic but otherwise negative. Barium lagged in the second and third portions of the duodenum and the normal markings of the *valvulae conniventes* were not present for some distance in the jejunum.

A number of stools examined were found to have the same general characteristics. They were of grayish color, soft consistency, foul odor, and contained a large amount of fat. Starch, muscle fibers, ova, parasites, pus, blood and mucus were absent. Occult blood was noted in traces.

The erythrocyte level on April 24, 1934, was 3.9 million, the hemoglobin was 74 per cent. Erythrocytes had a poor color, and were somewhat irregular in size. A definite macrocytosis was present. The white blood cell count was 4,200 and the differential count showed lymphocytes 46 per cent, juvenile forms 4 per cent, stab forms 4 per cent, and segmented cells 46 per cent. Definite deviation to the right was noted. The blood Wassermann test was negative. Blood calcium was 7 mg. per 100 c.c. of blood. Blood urea was 20 mg. per 100 c.c. On a fasting stomach, blood sugar was 89 mg. and rose to a maximum of 98 mg. in one hour after glucose ingestion. Stool culture on ordinary media was negative but was positive for a fungus on Sabouraud's media. Urine diastase was negative. Stomach acidity was within normal limits.

Treatment and Progress The patient was placed on a practically fat free, high protein, and low carbohydrate diet. Later medication was given at intervals consisting of viosterol 10 ggt. three times daily, 2 c.c. of liver extract intramuscularly three times weekly, calcium lactate 10 gr. three times daily and still later ventriculin with

iron On January 29, 1935, after nine months of the above treatment, the patient summarized her condition as very definitely improved but not satisfactory

On January 30, 1935, the patient was placed on desiccated duodenal extract in a dose of 10 gm daily This was soon increased to 15 gm and has been continued with a very few short interruptions for two years During this interval the patient has had no other medication but has continued to observe the dietary program previously mentioned

On January 29, 1935, the blood picture was as follows Erythrocytes 4 million Definite macrocytosis present Reticulocytes 0.5 per cent, white blood cells 3,900 Differential count Juvenile forms 10 per cent, monocytes 6 per cent, lymphocytes 40 per cent, rod forms 14 per cent, segmented cells 28 per cent, eosinophiles 2 per cent On February 15, 1935, the erythrocytes were 5 million This very definite improvement in the blood picture has been constantly maintained since that date In the same 16 day interval the blood calcium and phosphorus also increased to normal levels and have been maintained with few interruptions The stools have been free from an excess of fat except on a few occasions, particularly when the patient tried to take too much fat in her diet On such occasions the stools have been loose and the blood calcium and phosphorus have also been found at lower levels The symptoms of flatulence, abdominal distress, sore mouth and tongue, lack of strength, insomnia, nervousness, abnormal stools have not occurred for 18 months The last difficulty occurred for a short period in June 1935 The patient has made a slow but steady gain in weight and her appetite is very good She has been able to do her work without fatigue and is in better health than she has enjoyed for years The patient was last seen on January 18, 1937, at which time she had no complaints Her erythrocyte count was 5 million, and hemoglobin was 109 per cent

Case 7 Non-tropical sprue

History The patient, Mrs J V, aged 48, was seen on February 7, 1935, complaining of anemia, intermittent diarrhea of 32 years' duration, a burning sensation in the mouth and rectum, abdominal distress, flatulence, undernutrition, and insomnia Upon examination undernutrition was noted Face and neck were quite bronzed The tongue was smooth The abdomen was tympanitic Some soreness and restriction of motion were noted in the left shoulder and hypertrophic changes were found in the terminal interphalangeal joints The stools contained no parasites but were mushy and contained an excess of fat The stomach contents were without free HCl after histamine stimulation Blood calcium was 7 mg and phosphorus 3.3 mg per 100 c c of blood Erythrocytes were 3.8 million, hemoglobin 83 per cent (Sahli) Volume index was 1.09 White blood cells 6,150 Differential count Rod forms 10 per cent, segmented cells 37 per cent, eosinophiles 4 per cent, basophiles 0, lymphocytes 42 per cent, monocytes 6 per cent, juv forms 1 per cent Macrocytosis, anisocytosis, poikilocytosis, and polychromatophilia were present

The patient was given a diet restricted in fat, dilute HCl, and 15 gm of desiccated duodenal mucosa daily On this regime she felt an improvement as early as the fourth day On February 22, the fifteenth day of treatment, the erythrocytes were 4.9 million and the hemoglobin 85 per cent The patient continued to do nicely for a period of three months At the end of that time further effort to continue observations on the results of treatment were discontinued for the reason that the patient lived in a distant city and could not report

DISCUSSION OF CASES

A critical analysis of the case histories presented indicates that the therapeutic effect of desiccated duodenal mucosa is similar to, or even better than, the results obtained from the use of desiccated stomach preparations The dosage employed in the cases reported was in each instance much less

than the quantities recommended for the latter material yet the erythrocyte response amounted in all cases to 300,000 cells or more per week, whereas an increase of 100,000 cells per week is considered to be satisfactory with stomach preparations.

The reticulocyte response unfortunately could not be determined with sufficient frequency to absolutely establish the relative potency of the material employed and in no instance is there any assurance that the height of the reaction was recorded. In Case 1, however, an increase of 14.8 per cent occurred on the eighth day after administration of 15 gm. of desiccated duodenal extract. The initial erythrocyte count in this instance was 1.45 million. According to Bethell and Goldhamer's table for a similar initial count the height of the reticulocyte response after feeding 40 gm. of desiccated stomach mucosa daily should be 29 per cent. With less than half the dose, therefore half the expected increase of reticulocytes was obtained. In Case 4 with an initial count of 3.2 million the reticulocyte response at its height should be 3.1 per cent, after taking 40 gm. of stomach mucosa daily. In this case with 25 gm. of desiccated duodenal mucosa an increase to 5.9 per cent was found on the tenth day. The clinical improvement in every instance was satisfactory and normal erythrocyte levels were maintained in at least three cases for a sufficient time to exclude the possibility of spontaneous remission having occurred.

A study of six cases of gastrointestinal difficulty associated with anemia, diarrhea, and colitis has indicated that, in addition to its antianemic properties, the preparation has qualities which may be of considerable therapeutic value in the treatment of such conditions. The improvement noted may be due to the presence of intestinal ferments.

COMMENT

The above work it must be remembered deals with a material derived from the duodenal mucosa of swine. This cannot be considered in any way as direct proof that a similar antianemic substance may be found in the intestinal mucosa of man. A careful review of the literature, however, would indicate that such an assumption should be made. Castle's work with duodenal secretion should be carried further to show the effect on a primary anemia of the administration of human duodenal mucosa, or the response to the product of the interreaction between human duodenal mucosa and beef extract. It is possible that some chemical reaction or ferment activity may change or modify duodenal secretion so that in Castle's experiment negative results are obtained.

CONCLUSIONS

1. A study of the literature indicates a weakness in Castle's assumption that *intrinsic factor* is produced only in the stomach.
2. Many of the uncertainties arising from Castle's hypothesis may be

reasonably dispelled by the assumption that *intrinsic factor* is produced quantitatively in both the stomach and bowel

3 Proof that potent antianemic material is found in the duodenal mucosa of swine is presented

THE ORIGIN OF PAROXYSMAL TACHYCARDIAS AS DETERMINED BY THE ESOPHAGEAL ELECTROGRAM *

By A. McGEHEE HARVEY, M D , *Baltimore, Maryland*

IN order to differentiate clearly the various types of sudden increase in the cardiac rate electrocardiographic records are necessary. In view of the fundamental differences in the method of treatment employed in these instances of paroxysmal tachycardia an exact diagnosis is desirable. In many instances the auricular complexes are not clearly discernible in the three conventional leads, and the cardiac rhythm cannot be determined with certainty. For example, the difficulty in distinguishing paroxysmal auricular tachycardia and auricular flutter with one to one response is especially great.

The esophageal electrogram is of practical aid in the diagnosis of abnormalities of the auricular rhythm as the P-waves are large and clearly defined in these records. The method described by W. Hurst Brown¹ has been used in the study of the cardiac arrhythmias presented in this report. If care is taken to anesthetize thoroughly the pharynx with a 5 per cent solution of butyn no difficulty will be experienced in passing the electrode. In ambulatory patients the position of the esophageal electrode is checked by fluoroscopy. With the patient placed in the right anterior oblique position the cardiac outline is traced on a piece of tissue paper held in front of the fluoroscopic screen. The exact position of the electrode in relation to the posterior surface of the heart can be accurately recorded in terms of depth in centimeters from the teeth upon this outline. After this procedure has been carried out the electrode can be placed at the various points without fluoroscopic control. By averaging the results obtained by fluoroscopic control Brown found that the multiplication of the measurement in centimeters from the thyroid cartilage to the tip of the ensiform process by 1.33 always indicated the depth in centimeters from the teeth necessary to bring the electrode behind the left auricle. This method is used when fluoroscopy cannot be performed.

Three cases of paroxysmal supraventricular tachycardia, one case of paroxysmal ventricular tachycardia, and one of indeterminate origin have been studied in this manner. Before presenting them a brief description of the form of the normal esophageal record seems advisable.

When the esophageal electrode lies behind the left auricle the main characteristic of the P-wave is a sharp upstroke indicating electro-negativity of the small area just beneath the electrode. The onset of auricular activity is usually represented by a small upright or "extrinsic" deflection repre-

* Received for publication February 12 1937

From the Cardiographic Laboratory of the Department of Medicine, Johns Hopkins Hospital and University

senting the summation of activation of points in the auricle distant from the electrode. The downward deflection just before the sharp upstroke or intrinsic wave indicates the rapid approach of the excitation wave to the cardiac muscle lying in closest approximation to the electrode. Whenever the electrode is not lying over the auricle the sharp upstroke or intrinsic deflection will be absent. Figure 7B shows the form of the esophageal electrogram at various levels. There is no need to comment in detail on the form of the ventricular complexes in these records.

PAROXYSMAL SUPRAVENTRICULAR TACHYCARDIA

Case 1 M. B., a 63 year old white woman, had had an attack of palpitation followed by vertigo and loss of consciousness at the age of 18. She had had several similar attacks each year since that time, each sudden in onset and cessation, and varying in duration from several minutes to several days. She was first admitted to this hospital in 1924 when a diagnosis of auricular flutter was made. On two occasions the attacks were stopped by the use of quinidine. The cardiac rate was usually above 200 during the period of palpitation. Although several electrocardiograms were obtained while the fast rate was present, it was impossible to determine whether the fundamental rhythm was due to paroxysmal auricular tachycardia or paroxysmal auricular flutter with one to one response.

Five days before her admission in June 1936 while drinking iced water the patient noted the onset of palpitation and vertigo. During the next few days she grew progressively more dyspneic and was unable to sleep.

On admission the temperature was normal, the pulse rate 220 and the respiratory rate 30. Dyspnea and cyanosis were prominent and the neck veins were engorged. There were arteriosclerotic changes in the retinal and peripheral vessels. Chronic bronchitis and emphysema were present, and many medium moist râles were heard at the lung bases. The heart was slightly enlarged. The sounds were of fair quality. The blood pressure was 100 mm Hg systolic and 90 diastolic. The liver was enlarged, but no edema was present. A diagnosis of arteriosclerotic heart disease with congestive heart failure was made.

An esophageal electrode was passed without difficulty. The records obtained showed paroxysmal supraventricular tachycardia and not auricular flutter.

After 25 mg of mechohyl the rhythm reverted to normal, a moderately severe attack of asthma ensued, and auriculo-ventricular nodal rhythm with inversion of the T-waves was present for a short while.

Interpretation of the Electrocardiograms Figure 1 A This is a record showing the three conventional leads. The rate is 75 and the P-R interval 0.13 sec. The QRS complexes are of low amplitude and thickened. Very small biphasic T-waves are present in each lead. B The three conventional leads during an attack are presented here. The rhythm is regular at a rate of 230 per minute. It is difficult to be certain of the presence of any regularly spaced P-waves. C and D A simultaneous recording of Lead II and the esophageal electrogram (C) shows the sharp upstroke of the P-wave and the form of the ventricular complex. Record D taken during an attack shows several points of interest. Whereas in the normal esophageal record auricular activity was present for some time before the excitation wave passed beneath the electrode, the electrode was directly over the origin of the impulse during the tachycardia as the sharp upstroke or "intrinsic" wave is the first evidence of auricular activity. The P-wave falls on the upstroke of the T-wave soon after the termination of QRS complex. The P-R interval is longer than in the previous records. These findings suggest that an auriculo-ventricular nodal paroxysmal tachy-

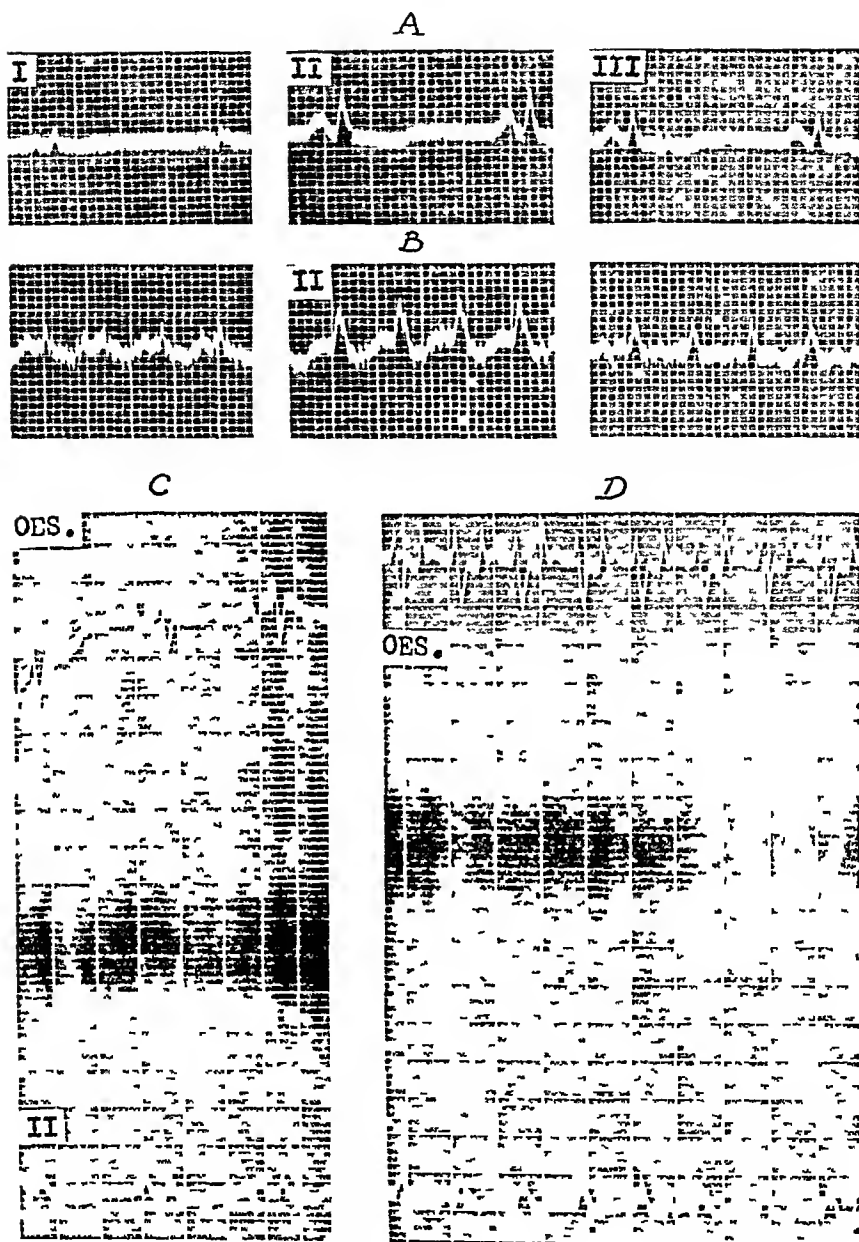

FIG 1 Standardization 1 mv = 5 mm Heavy vertical lines in the curves mark the time in 0.2 sec intervals

cardia is present. One cannot be certain of this, however, as a delayed auriculo-ventricular conduction time is not infrequent in the presence of such a rapid cardiac rate. The form of the QRS complex is the same in each record. Particularly striking is the ease with which the P-waves are visualized in the esophageal curve of record *D* in contrast to the confusion encountered in the simultaneously recorded Lead II.

Figure 2 This unusual record shows the onset of an attack of tachycardia in this patient. The change in the form of the auricular complex with the onset of the fast rhythm is clearly visualized. Lead II is simultaneously recorded.

FIG 2

Case 2 Paroxysmal supraventricular tachycardia L B, a 37 year old white housewife, came to the Dispensary in February 1936, complaining of attacks of tachycardia. The attacks began eight years previously, shortly before her marriage. They increased in number during her first pregnancy, and have occurred from three to five times weekly since then. Sneezing, bending over, or any sudden effort usually was the precipitating factor. The tachycardia most often lasted only a few minutes, but occasionally persisted for two or three days. The attacks became more frequent and severe during the month prior to her visit. The past history was non-contributory.

The patient was a well developed and nourished, healthy-looking woman who felt perfectly well when the tachycardia was absent. The general physical examination showed nothing abnormal. The heart was not enlarged. The sounds were of good quality, no murmurs were audible, and the blood pressure was 110 mm Hg systolic and 70 diastolic. A complete diagnostic survey revealed no foci of infection or any causative factor. There was no evidence of organic heart disease.

The patient was able to produce an attack by repeatedly bending over and touching her ankles, thus it was possible to make a complete study of the nature of the tachycardia. It was discovered that light pressure in the region of the right carotid sinus stopped the tachycardia immediately. The patient was taught to perform this simple maneuver. At a visit six months later she stated that no difficulty had been encountered in stopping each attack quickly in this manner.

The Electrocardiograms Figure 3 *B* This record was taken shortly after the cessation of an attack. The rate is 88, and the P-R interval 0.18 sec. The P-waves in Lead II are notched, and the T-waves are all of small amplitude. *A* The electro-

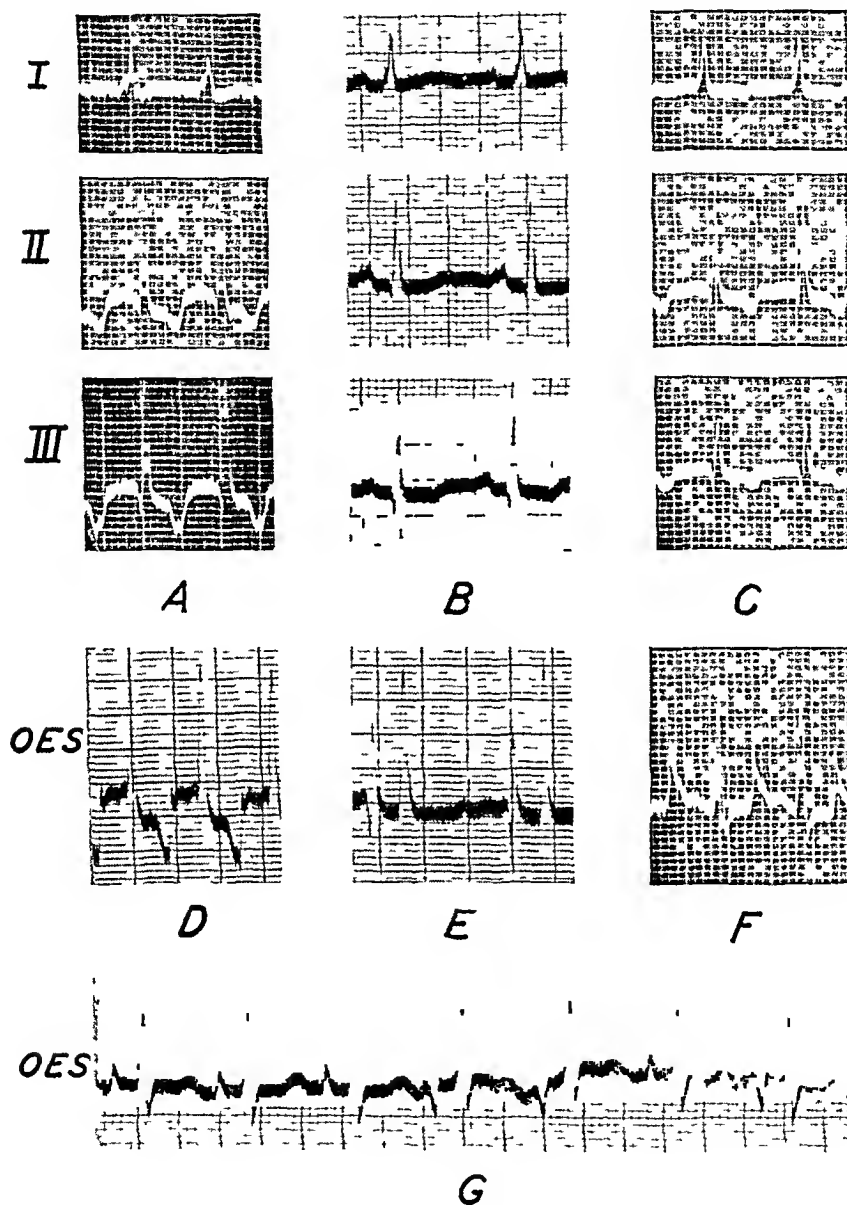

FIG 3

cardiogram during this attack reveals a rate of 150 which is quite regular. In Leads II and III the P-waves are superimposed on the end-deflection of the ventricular complex. The P-R interval is quite definitely longer than in the records taken at a normal rate. *C* This record taken during a second paroxysm shows a P-wave of a different character. The rate is only 136, and the auriculo-ventricular conduction time is slightly longer. These differences suggest that the position of the ectopic focus varied in each of these attacks. *E* In this normal esophageal record the P-waves are quite

distinct *D* and *F* show the form of the esophageal lead in two separate attacks. In each the esophageal electrode was at the same level as in the normal record. In *F* the first evidence of auricular activity is a sharp upstroke while in record *D* changes due to activity at a point away from the electrode are visible before the intrinsic wave appears. *G* This figure furnishes an explanation for the variable form of the records taken during periods of tachycardia. While this esophageal electrogram was being taken the patient held her breath and the position of the electrode remained the same.

The changes in the form of the auricular complexes in successive cycles are apparent. These variations are probably due to a shift in the pacemaker. Thus in this patient there is more than one ectopic focus from which the paroxysms of tachycardia arise.

Figure 4 This attack was promptly stopped by pressure in the region of the right carotid sinus. The characteristic post-paroxysmal pause and the gradual return of the P-R interval to normal are illustrated. An extra-systole (P B) occurred during the pause. Lead II is not clearly recorded as the patient moved while the record was being taken.

FIG 4 The termination of an attack of paroxysmal tachycardia by carotid sinus pressure

Case 3 Paroxysmal supraventricular tachycardia. F W, a 49 year old white male clerk, had had attacks of paroxysmal tachycardia for a period of 29 years. From the ages of 8 to 12 he had several attacks of rheumatic polyarthritis. The attacks of tachycardia were of sudden onset and termination, lasting from a few minutes to several hours and occurring one to two times a week. They were increased in frequency and duration during periods of constipation and upper respiratory infection. On various occasions the attacks had been stopped by bending over, by a blow to the precordium, or by pressure on the eyeballs.

The patient was well developed and nourished. There were no evidences of cardiac insufficiency. The heart was slightly enlarged both to the right and left. The typical signs of mitral stenosis and aortic insufficiency were noted.

During an attack the rate suddenly increased to 187. The patient's only symptom was palpitation. After electrocardiographic records were obtained the attack was stopped by pressure on the eyeballs. Quinidine has been administered in prophylactic doses, and since that time the attacks have been both less frequent and shorter in duration.

D
FIG 5

Electrocardiograms Figure 5 *A* The normal electrocardiogram shows a rate of 75 with a P-R interval of 0.19 sec. There is a left axis deviation. The QRS complex in Lead III is slurred. T_1 is biphasic, T_2 and T_3 upright. One ventricular extrasystole is present in Lead II. *B* This record taken during a period of paroxysmal auricular tachycardia has a rate of 194. The P-waves and the T-waves are superimposed. The ventricular complexes are supraventricular in type. There is alternation in the amplitude of the QRS complexes. *C* The normal esophageal lead shows a typical auricular complex composed of a small upright wave succeeded by a steep downward deflection as the excitation wave approaches the region in apposition to the electrode. Late in the complex the sharp upstroke or "intrinsic" wave appears. The duration of the intraventricular conduction time is 0.13 second in this record. The simultaneously recorded Lead II shows no such prolongation of the QRS duration. *D* The esophageal electrogram during an attack shows clearly defined P-waves in contrast to the conventional leads. The rate here is only 176. The P-R interval is only 0.15 second as compared to 0.19 in the records with normal rhythm.

Case 4 Paroxysmal ventricular tachycardia. C. S., a 15 year old colored girl, came to the hospital on June 19, 1936 complaining of a sensation of choking and rapid heart action. She had always been healthy. There was no history of tonsillitis, rheumatic fever, or chorea. She stated that in August 1934, and again one year later she had had a similar illness lasting about 10 days. The present attack began one week before admission, and the patient had vomited several times each day.

The temperature was 100.6°, the pulse rate 220, and the respirations 38. The patient was well developed and nourished. She seemed uncomfortable but not acutely ill. The neck veins were a little full, and very rapid venous pulsations were visible. The heart was at the upper limit of normal in size. There was a diastolic shock in the second left interspace, and a prominent pulsation was visible there. The first sound was snapping in quality, and a triple rhythm was present at the apex. There was no evidence of cardiac insufficiency. The remainder of the physical examination was negative.

Following the administration of apomorphine the rate became normal, but the tachycardia reappeared within a few hours. The electrocardiogram revealed a tachycardia which was ventricular in origin. Mecholyl was tried but had no effect. About 24 hours after admission, after one gram of quinidine had been administered, the patient had a sudden stabbing pain over the precordium following which the heart rate became normal. After reversion a systolic apical murmur was audible, but diastole was clear. The roentgen-ray showed an accentuation of the second curve on the left. The position of the barium-filled esophagus was normal indicating that no pronounced enlargement of the left auricle was present. The diagnosis was paroxysmal ventricular tachycardia, with questionable rheumatic heart disease. The patient was discharged and advised to take a prophylactic dose of quinidine daily. No further attacks have occurred.

The Electrocardiograms Figure 6 *A* The record after reversion to normal sinus rhythm shows a rate of 107 with a P-R interval of 0.14 sec. The P-wave in the second lead is of comparatively large amplitude. The QRS complexes in Leads II and III are thickened. There is arching of the S-T intervals and all of the T-waves are inverted. In later records the left axis deviation disappeared, and the T-waves became upright. *B* This record shows the ventricular tachycardia with a rate of 230. No P-waves are visible. *C* and *D* These records show the esophageal electrograms, the first taken while normal sinus rhythm was present. The second taken during an attack shows the striking change which has taken place in the ventricular complexes. Again no auricular waves can be seen. The electrode was at the same level in each instance.

Case 5 Paroxysmal tachycardia of indeterminate origin. A 10 year old col

ored girl came to the hospital on January 2, 1937, because of a rapid heart rate of two hours' duration. There was no history of rheumatic fever or chorea. During the first year of life the patient had had severe rhinopharyngitis complicated by otitis media and later acute tonsillitis with a membrane suggestive of diphtheria. Acute

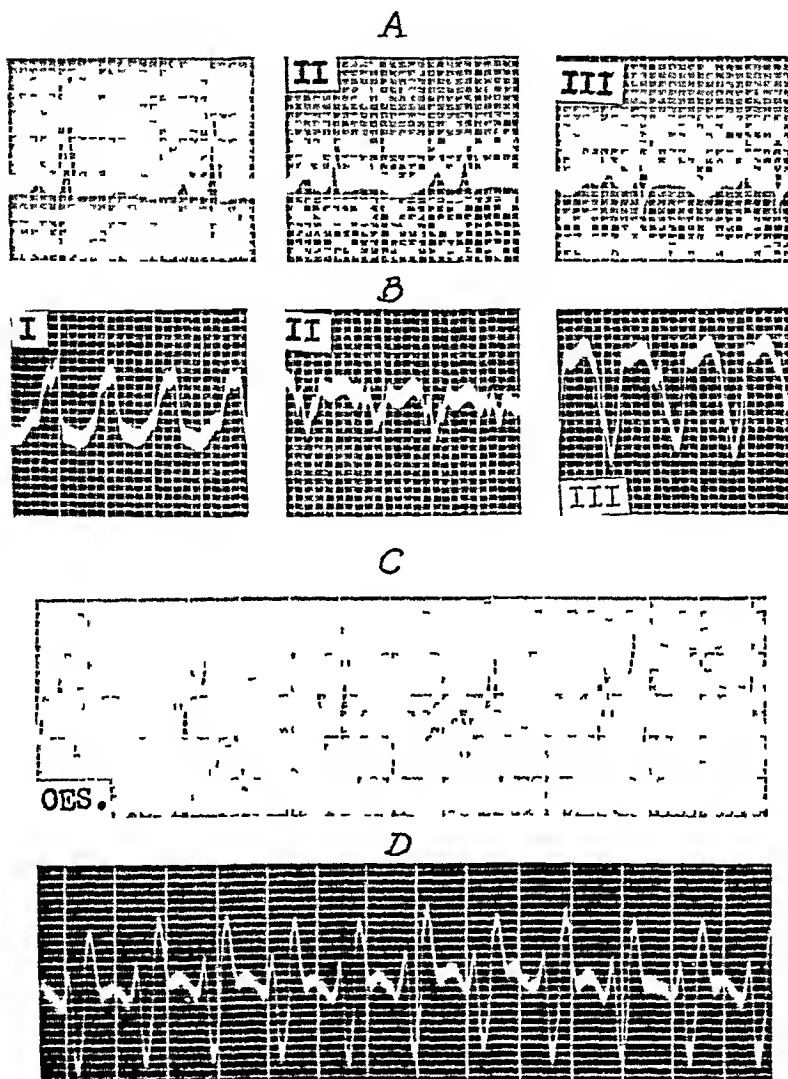

FIG 6

cervical adenitis developed one month later, which had to be drained. At five years of age she had measles and two months later laryngeal stridor which necessitated tracheotomy. Culture of the throat showed B hemolytic streptococci but no diphtheria bacilli. An electrocardiogram taken at that time showed frequent ventricular extrasystoles. A tonsillectomy was done later, and the patient was well until April 1935, when she was admitted with lobar pneumonia. The heart was normal. The basal metabolic rate was not elevated.

In June 1936 she came to the hospital complaining of precordial pain. The pulse was so fast that it could not be counted. Before an electrocardiogram could be taken the cardiac rate had dropped to 94. An occasional ventricular extrasystole was present. Following this the patient was quite well until her present attack.

The temperature was normal. The eyes were a little prominent. The tonsils were cleanly removed. The lungs were clear. The heart was not enlarged. During the attack a rapid regular rhythm with a rate of 230 was present. The sounds were of good quality. The neck veins were engorged. The remainder of the examination was negative. When the cardiac rate had returned to normal, no murmurs could be heard.

After the electrocardiograms were taken efforts were made to stop the attack by vagal stimulation such as eye-ball pressure, carotid sinus pressure and finally mecholyl. All were unsuccessful. About five hours after the onset, after 0.3 gm. of quinine sulphate had been given, the pulse rate was found to be 120. It was almost certainly a spontaneous reversion to normal rhythm.

The Electrocardiograms Figure 7. *A* This is the normal record with a rate of 91 and an auriculo-ventricular conduction time of 0.14 second. There is left axis deviation. The T-waves are upright. *B* The normal esophageal electrograms taken at the levels indicated illustrate the sequence of changes in the auricular complex. *C* and *D* These records taken during the period of ventricular tachycardia contrast the ease with which the auricular complex is recognizable in the esophageal record in comparison to the conventional leads. The sharp upstroke is greatest with the electrode placed at 31 cm.

Without further evidence it is impossible to determine accurately whether this tachycardia was ventricular in origin with retrograde P-waves, or auricular with delayed intraventricular conduction. Only by means of a double esophageal electrode to determine the direction of spread of the auricular complex, an electrocardiographic record of the onset or termination of the attack, or by observation of the effect of rebreathing of oxygen on the form of the ventricular complex could further helpful information be obtained. The patient has had no further attacks during which these procedures could be carried out.

DISCUSSION

The electrocardiographic records taken in these patients demonstrate the greatest ease with which the auricular complex can be recognized during an attack of paroxysmal tachycardia by means of an esophageal lead.

Other methods of amplifying the auricular deflection so that its form could be determined in doubtful cases have been suggested. McGuire and Foulger² in 1931 described three cases in which they used a needle electrode inserted beneath the skin at the second and fifth right intercostal spaces near the sternum. By this means the P-waves were made more prominent, and the true nature of the arrhythmia could be determined.

Roth³ employed a right pectoral chest lead to record tracings of auricular activity. The right arm electrode was placed on the right arm, and the principal or left arm electrode in the right pectoral region. A case of auricular fibrillation and one of mitral stenosis are recorded in which the auricular waves were more clearly visualized than in the conventional leads.

In two of the cases of supraventricular tachycardia included in the present report the auriculo-ventricular conduction time was longer than that recorded during normal sinus rhythm. Although delay in conduction in these cases is not frequent it does occur. It is sometimes difficult to determine definitely whether the abnormal pacemaker is situated in the auricle or whether an auriculo-ventricular nodal tachycardia is present.

A

B

C

D

FIG 7

Case 2 is of interest because of the shift which occurred in the position of the auricular pacemaker. The form of the P-wave changed conspicuously, but there was only a slight variation in the P-R interval. White⁴ published electrocardiograms illustrating a variation in the position of the pacemaker as shown by the shape of the P-wave, and the length of the P-R interval. In the same report he describes a case of paroxysmal tachycardia.

arising in or very near the sino-auricular node which did not show an absolutely abrupt onset or offset. In case 2, of this series, although the onset and termination were prompt, there was a gradual acceleration of the rate to a maximum level followed by a gradual decline before the termination in some of the attacks. In this case the variation in the rate and the P-R interval in different attacks leads one to believe that there was more than one ectopic focus from which they arose.

In comparison with the incidence of paroxysmal supraventricular tachycardia, cases in which the ectopic focus is in the ventricle are uncommon. In contrast to the former group they are usually associated with organic heart disease, and in many instances occur after coronary thrombosis. The patient reported here was a young colored female in whom no definite organic heart disease could be discovered.

SUMMARY

The esophageal electrogram is helpful in detecting the auricular complexes when these are difficult to outline in the conventional leads.

Three cases of paroxysmal supraventricular tachycardia, one case of paroxysmal ventricular tachycardia, and one of indeterminate origin are presented. The appearance of the normal electrocardiogram and the esophageal electrogram is compared in each case.

Records are shown illustrating the onset and termination of paroxysmal auricular tachycardia. The esophageal lead and the conventional Lead II were recorded simultaneously.

STUDIES ON EXPERIMENTAL HYPERTENSION

V THE PATHOGENESIS OF EXPERIMENTAL HYPERTENSION DUE TO RENAL ISCHEMIA

By HARRY GOLDBLATT, M D , C M , *Cleveland, Ohio*

THE production of persistent hypertension in dogs and monkeys has been reported in previous communications¹⁻⁴ This was accomplished by constricting the main renal arteries by means of a special silver clamp devised for the purpose In some of the dogs hypertension of severe degree has now existed for more than five years The type of hypertension produced by this method depends upon the degree of constriction of the renal arteries When the constriction is not very great, there is little or no disturbance of renal function accompanying the hypertension and it resembles benign hypertension in man When the constriction is very severe, there is often accompanying damage of renal function which may also be severe Such animals may die in uremia so that in this respect the hypertension resembles malignant hypertension in man Constriction of splenic and of femoral vessels had no effect on blood pressure² This is in keeping with the negative results obtained by Longcope and McClintock⁵ from constriction of the superior mesenteric artery These findings have been confirmed for the dog by other investigators⁶⁻¹⁸ The present report deals with experiments designed to determine the mechanism whereby the reduction of blood flow to the functioning components of the kidney, that is, renal ischemia, induces the development of hypertension

That some pathological change in the kidney may be the cause of some forms of cardiovascular disease in man has been suspected on the basis of clinical observations and pathological findings from the time of Bright^{19, 20} That a pathological change in the kidney may initiate hypertension in man, especially the type that is associated with so-called diffuse vascular disease, has been recognized by some investigators for more than 50 years, since the existence of hypertension was first recognized This view is still upheld by some, like Fahr,²¹ who, on teleological grounds, regards the hypertension as compensatory to the reduced blood flow through the kidney, and by Volhard,^{22a, 22b} on the basis of a humoral mechanism of renal origin, for at least the so-called malignant type of hypertension It is opposed by others, like Kylin,^{23, 24} who does not admit a primary renal origin even for the hypertension that accompanies glomerulonephritis The mechanism whereby the kidneys produce their effect is still regarded as unsolved even by those who

These studies were supported by the Beaumont-Richman-Kohn Fund

consider that these organs can play a primary part in the origin of hypertension

Many experiments have been performed to determine whether the kidneys can be the primary site of origin of hypertension in animals

A SUMMARY OF OTHER EXPERIMENTS DESIGNED TO DETERMINE THE POSSIBLE RENAL ORIGIN OF HYPERTENSION

Bilateral nephrectomy

- Mosler,⁷ (1912) Used rabbits Insignificant elevation of blood pressure
 Backmann,⁸ (1916) Used cats No elevation of blood pressure
 Cash,²⁷ (1926) Used dogs No elevation of blood pressure
 Hartwich,²⁸ (1930) Used dogs No elevation of blood pressure
 Harrison, Blalock and Mason,¹¹ (1936) Used dogs No elevation of blood pressure in 16 out of 18 dogs

Reduction of the amount of functioning renal tissue

- Grawitz and Israel,¹ (1879) Used rabbits Slight hypertrophy of heart, interpreted by the authors as due to hypertension
 Passler and Hemeke,¹⁰ (1905) Used dogs Slight elevation of blood pressure
 Backmann,⁸ (1916) Used cats Slight elevation of blood pressure
 Allen and collaborators,^{31, 32, 33} (1923) Used dogs Slight temporary elevation of blood pressure
 Mark,^{41a, 41b} (1925, 1928) Used dogs Slight elevation of blood pressure
 Anderson,³¹ (1926) Used rabbits No elevation of blood pressure
 Friedman and Wachsmuth,³⁵ (1930) Used dogs No elevation of blood pressure
 Chanutin and Ferris,³⁶ (1932) Used rats Great elevation of blood pressure
 Ryland, D A and Dock, W,³⁷ (1935) Used rats Great elevation of blood pressure

Reduction of amount of renal substance by coagulation necrosis due to ligation of branches of renal arteries

- Janeway,^{38, 39} (1908), assisted by Carrel⁴⁰ Used dogs Slight elevation of blood pressure
 Mark,^{41b} (1928) Used dogs No elevation of blood pressure

Reduction of amount of renal substance by partial renal excision and unilateral nephrectomy combined with coagulation necrosis of part of the remaining kidney by ligation of branches of renal artery

- Cash,⁴² (1924) Used dogs Slight to moderate temporary elevation of blood pressure

- Mark and Giesendorfer,⁴³ (1930) Used dogs Moderate temporary elevation of blood pressure
- Ferriis and Heynes,⁴⁴ (1931) Used dogs Slight temporary elevation of blood pressure

Destruction of renal substance by irradiation of kidneys with roentgen-rays

- Hartman, Bolliger and Doub,⁴⁵ (1929) Used dogs Moderate elevation of blood pressure
- Page,⁶ (1935) Used dogs Moderate elevation of blood pressure

Renal infarction due to multiple emboli

- Senator,⁴⁶ (1911) Used cats Injected liquid paraffin into renal arteries No rise of blood pressure
- Cash,⁴² (1924) Used dogs Injected insoluble Berlin blue No elevation of blood pressure
- Apfelbach and Jensen,⁴⁷ (1931) Used dogs Injected particles of charcoal into renal arteries No elevation of blood pressure

Scaiff and McGeorge,⁵⁹ (1937) Used rabbits Injected sodium oxalate No elevation of blood pressure

In the earlier investigations summarized above the hypertension that was observed was usually slight and lasted from only a few hours to several days. Some of the later investigators also reported the development of hypertension of slight or moderate degree and of short duration while others succeeded in producing moderate or severe hypertension of longer duration. Under practically every heading contradictory reports occur. These differences are partly due to the various methods, including cardiac hypertrophy, used for determining the existence of hypertension, the various types of animal employed and the slight changes of blood pressure which were regarded as significant by some and not by others. For some of the opposite results there is no obvious explanation. While the results of these experiments do indicate that various pathological changes in the kidneys can, in some way, play a primary part in initiating some degree of hypertension in animals, yet by none of these methods was a condition produced in the kidney which is comparable to that of the kidney in human hypertension that is associated with arteriolar disease. To reproduce a state resembling the condition of the kidney in arteriolar disease, any method must effect a decreased flow of blood to the functioning elements of this organ. Loesch⁴⁹ approximated this condition by completely occluding the circulation to and from the kidneys, and probably the ureter, for a short while, every two or three days, by clamping the entire pedicle of explanted kidneys. However, there is no good reason for believing that such intermittent occlusion of the arterial blood supply to the kidneys as well as complete interference with the return of venous blood from the kidneys reproduces the functional effects of arteriolar disease in the kidney. If the arteriolar disease of the kidney be responsible for the origin of hypertension then the more likely mechanism of its action is persistent reduction of blood flow to the functioning elements of this organ. The only method which would reproduce this exactly is one that would result in functional or organic narrowing of the arterioles of the kidney. No one has yet succeeded in producing either generalized arteriolar sclerosis or arteriolar sclerosis limited to the kidneys. The closest approach, therefore, to the functional effects of arteriolar dis-

ease on the kidneys has been accomplished by reducing the calibre of the main renal arteries alone,¹⁻⁴ with resultant renal ischemia, due to persistent reduction of blood flow into the organs. It was considered possible, therefore, that an elucidation of the mechanism of development of this type of experimental hypertension might make some contribution to our knowledge of the pathogenesis of the hypertension in man that is associated with arteriolar sclerosis and consequent ischemia of the kidneys. This is to be regarded as a preliminary communication on this part of the subject.

EXPERIMENTS

The following experiments were performed for the purpose of elucidating the mechanism of hypertension due to renal ischemia.

Release or Removal of the Clamp In six dogs, one or both clamps were released or removed some time after hypertension due to renal ischemia had

FIGURE 1 Dog 1-40 Female 13.4 Kg

● = Systolic blood pressure, van Leersum carotid loop method RK = Right main renal artery severely constricted LK = Left main renal artery severely constricted LKR = Left clamp completely released but left on the artery

The blood pressure, which had risen to a very high level after the constriction of the second renal artery, fell to normal in about one month after the release of the clamp on this artery.

been established. Quite promptly, but after a variable period, the blood pressure in these animals returned to the original level. In Dog 1-40 (figure 1), release of one clamp was followed by a rather slow fall of the blood pressure to the original level. In this animal there was no impairment of renal function. In Dog 2-67 (figure 2), after unilateral nephrectomy (LN), severe constriction of the main artery of the remaining kidney (RK₁) resulted in severe hypertension and severe impairment of renal function. When the clamp was released, (RKR₁) blood pressure and renal function promptly returned to normal. Reconstriction of the artery (RK₂) again resulted in hypertension and uremia. Slight release of the constriction (RKR₂) relieved the uremia but the blood pressure remained slightly elevated.

FIGURE 2 Dog 2-67 Female 136 Kg

● = Mean blood pressure, mm Hg, ○ = blood urea mg per 100 cc plasma. LK = Left main renal artery severely constricted. The blood pressure became greatly elevated. During about ten months after this the blood pressure remained elevated but gradually fell to a moderately elevated level. LN = The ischemic left kidney was excised and the blood pressure promptly fell to the normal level. RK₁ = The right main renal artery was severely constricted. The blood pressure became elevated and uremia developed. RKR₁ = The clamp on the right main renal artery was released. The blood pressure, blood urea, creatinine and non-protein nitrogen promptly returned to normal. RK₂ = The right main renal artery again constricted. Elevated blood pressure and uremia again resulted. RKR₂ = The right main renal artery partly released. Blood pressure dropped temporarily, then rose again and remained elevated. The animal developed severe uremia. K = Killed.

Removal of the Ischemic Kidney During the Period of Hypertension Following the Constriction of One Main Renal Artery. It was shown in the original communications^{1,2} that hypertension of some degree follows the constriction of the main renal artery of only one kidney but that after a variable period the blood pressure tends to return to the original level. In some dogs the blood pressure remains elevated for a considerable period following unilateral renal ischemia. In one dog, 2-67 (figure 2), the mean

blood pressure remained at a higher level than normal for about nine months following the constriction of the main renal artery of only one kidney. During this period there was no impairment of renal function. After the removal of this kidney (LN) the blood pressure promptly fell to the normal level. Severe constriction of the main renal artery of the remaining kidney

FIGURE 3 Dog 2-50 Female 17.8 Kg

● = Mean blood pressure, mm Hg. RK = Right main renal artery moderately constricted. RN = Right nephrectomy at a time when the mean blood pressure was elevated resulted in its prompt return to normal. LK = Severe constriction of main renal artery of left kidney. This was followed by very high elevation of mean blood pressure. + = The mean blood pressure at this time was more than 300 mm Hg. K = Killed.

(RK₁) resulted in reelevation of mean blood pressure and impairment of renal function. In two other dogs also, at the height of elevation of blood pressure, after moderate to severe constriction of the main renal artery of one kidney, this ischemic kidney was excised. Dog 2-50 (figure 3), illus-

trates what happened in these animals. As in the case of Dog 2-67 (figure 2), removal of the ischemic kidney (RN) was followed by a prompt return of the mean blood pressure to the original level. Constriction of the main renal artery of the remaining kidney (LK) was followed by a prompt re-elevation of blood pressure which persisted. The results of these experiments indicate the importance of ischemia as the pathologic change and the kidney as the primary site of origin of this type of hypertension.

FIGURE 4 Dog 3-28 Male 166 Kg

● = Mean blood pressure, mm Hg ○ = Blood urea nitrogen mg per 100 c.c. plasma
BN = Bilateral nephrectomy The blood pressure did not become elevated D = Died

Bilateral Nephrectomy If uremia alone were the cause of hypertension, then the removal of both kidneys, which is always followed by the development of uremia, should also, invariably, be followed by the development of hypertension.

In five dogs, both kidneys were removed. In three, bilateral nephrectomy was performed at one time and in two, the nephrectomies were separated by an interval of a week or longer. Most of the animals appeared in good condition for about 48 hours following the operation. All the animals died

in uremia but the blood pressure did not rise during the period of survival which varied from two to five days. Figure 4, Dog 3-28, illustrates one of these experiments. This finding is in keeping with the results obtained by other investigators^{11, 25, 26, 27, 28}

Occlusion of the Main Renal Artery of Both Kidneys It might be considered that occlusion of both main renal arteries would be equal to, and give the same results, as bilateral nephrectomy. This is not the case. In

FIGURE 5 Dog 2-63 Female 162 Kg

● = Mean blood pressure, mm Hg ○ = Blood urea, mg per 100 cc of plasma
 RLKC = Both main renal arteries occluded The blood pressure rose to quite a high level
 D = The animal died in uremia

four dogs the main renal artery of both kidneys was clamped completely at one operation and in two dogs the occlusion of the second artery was carried out after an interval of a week or longer. The complete occlusion of one

main renal artery was not followed by either uremia or a significant elevation of blood pressure. In all four animals, however, simultaneous occlusion of the main renal artery of both kidneys was followed by the development of severe uremia and slight or moderate elevation of the blood pressure. The degree of hypertension in the animals with both renal arteries occluded was not as great as in dogs with both main renal arteries only moderately or

FIGURE 6 Dog 2-57 Female 18.4 Kg
● = Mean blood pressure, mm Hg ○ = Blood urea, mg per 100 cc of plasma
■ = Blood creatinine mg per 100 cc of plasma RLKC = Right and left main renal arteries occluded The blood pressure showed a moderate elevation following the occlusion of the arteries D = The animal died in uremia

severely constricted. The period of survival was about the same as that of the bilaterally nephrectomized animals. In the animals with both main renal arteries occluded, as in those bilaterally nephrectomized, the shock of the operation was evidently not great and for about 48 hours they seemed in

excellent condition Both groups survived about the same period and all developed severe uremia, yet the animals with both arteries occluded did show a significant elevation of blood pressure which is illustrated for three of the dogs in figures 5, 6 and 7, while the nephrectomized animals failed to show a rise of blood pressure In Dog 2-65, as a control, all of the arteries to the spleen were tied off completely (figure 7), some time before

FIGURE 7 Dog 2-65 Female 152 Kg

● = Mean blood pressure, mm Hg ○ = Blood urea nitrogen mg per 100 cc of plasma SpC = Splenic arteries occluded There was no significant rise of blood pressure after this procedure RLKC = Right and left main renal arteries occluded After this there was a moderate elevation of blood pressure D = The animal died in uremia

the renal arteries were occluded The occlusion of the splenic vessels was not followed by a significant elevation of mean blood pressure When both main renal arteries were occluded (RLKC) (figure 7), the blood pressure became slightly elevated severe uremia developed and the animal died

That a dog can survive for a long time the occlusion of both main renal arteries, provided the occlusion is not accomplished abruptly, has been well shown by four animals, in which the occlusion was accomplished in two or more stages One dog has proved this very strikingly At the second clamping of both main renal arteries carried out successively about one year after the initial partial constriction both main renal arteries were occluded This animal survived the complete occlusion of both main renal arteries for four years Hypertension of severe degree persisted during the entire

period and renal function, as shown by urea clearance, was only slightly affected. At autopsy, one kidney was very small and the other only moderately reduced in size. No accessory arteries were found except those that entered the kidney through the capsule. Other experiments of this kind, to be reported later, are being carried out to determine the exact source and extent of the supply of blood to such kidneys.

DISCUSSION

As in the case of partial constriction of both main renal arteries,² the hypertension which follows occlusion of both main renal arteries can be explained by a possible nervous reflex from the kidney by way of the central nervous system to the peripheral vasomotor apparatus or by some humoral mechanism, or by a combination of both mechanisms.

That hypertension due to occlusion of both renal arteries is not due to a nervous reflex from the kidney is indicated by the fact that in some of these animals the renal pedicle was carefully denervated before the clamp was applied. It has also been shown by other investigators,^{6, 10} and we have confirmed this, that renal denervation does not interfere with the development of experimental hypertension due to partial constriction of the main renal arteries. Section of the splanchnic nerves in the thorax, combined with excision of the lower four thoracic sympathetic ganglia, does not interfere with the development of hypertension or permanently reduce the hypertension produced by renal ischemia.⁴ In an investigation soon to be published in collaboration with Dr. W. B. Waitman, it will be shown that section of the anterior nerve roots, from the sixth dorsal to the second lumbar inclusive, also does not interfere with the development of hypertension or permanently reduce the hypertension produced by renal ischemia. Finally, Freeman and Page¹⁰ have shown that total sympathectomy does not interfere with the development of hypertension due to bilateral renal ischemia. These results are not to be interpreted as evidence or proof that the surgical procedures being practised on human beings with hypertension are not justifiable and that no improvement is to be expected from these procedures. What they do show is that in experimental hypertension, due to the permanent renal ischemia effected by the clamps, section or excision of various portions of the nervous system controlling a large part of the vasomotor mechanism of the abdominal organs, does not result in prevention or reduction of this type of experimental hypertension. These experiments serve to emphasize the importance of the reduction of the circulation to the functioning components of the kidney rather than a primary effect on the general vasomotor mechanism of the abdomen as the cause of this type of hypertension. This is in keeping with the views of Prinzmetal and Wilson⁶¹ and of Pickering⁶² about the secondary part played by the vasomotor mechanism in human hypertension. In man it is at least possible that as a result of some or all of the surgical procedures being practised on the

nervous system for the cure of hypertension, actual improvement of the circulation to the functioning components of the kidney may occur. Dilatation of renal arterioles without fixed organic changes in their walls might occur in some cases, as a result of these procedures. Since, in man, there is frequently no narrowing of the large renal vessels to interfere with the flow of blood into the kidney, it is at least conceivable that improved circulation to the functioning components of the kidney may follow as a result of dilatation of arterioles. This improvement of renal circulation could then account for the fall of blood pressure which has been observed in about the same rather small percentage of cases treated by the various surgical procedures on the nervous system. This view is in agreement with that of Peet⁶⁹ on the mode of action of resection of the splanchnic nerves in lowering the blood pressure in human beings with hypertension. It is not, however, the view that is generally accepted by those who have been performing operations on the nervous system for the cure of hypertension in man⁶³⁻⁷⁵. They prefer to regard the improvement following section or excision of the nerves as due to the elimination of their control over the corresponding portion of the vasomotor mechanism. The same improvement of the circulation cannot happen, or can happen to only a very limited degree, as the result of increased dilatation of the arterioles in the experimental kidney, as long as the main renal artery remains constricted by the clamp. These observations do minimize the importance of the effect of the vasoconstrictor mechanism in the abdomen in hypertension due to renal ischemia, because the removal of this mechanism by the various surgical procedures does not prevent or cure the hypertension as long as the clamps remain applied and the blood flow to the functioning components of the kidneys remains unimproved.

If the mechanism whereby constriction of the main renal arteries produces its effect on blood pressure be humoral and of renal origin then, in the case of the hypertension which also follows occlusion of both main renal arteries, it must be assumed that the natural accessory circulation through the capsule which may become more prominent in these circumstances, is sufficient to wash some hypothetical "effective substance" into the systemic circulation through the main renal veins. The term "effective substance" will be used in this paper to avoid commitment to the existence of a direct pressor substance rather than one which acts indirectly to produce the pressor effect. The effective substance, for example, might act synergistically with a known pressor hormone from an endocrine organ, such as the hypophysis or adrenal. It is also possible for the hypothetical effective substance from the kidney to act by sensitizing the contractile elements of the arterioles to the action of the pressor hormone or the reverse may be the case. The effective substance might also produce its effect by neutralizing or reducing the amount of a hypothetical depressor substance circulating in the blood. That there may be an effective substance from the kidney is indicated by

reports of the pressor effect of extract of ischemic kidneys from dogs with experimental hypertension,^{11, 13, 17} and of arteriosclerotic kidneys¹³ from human beings with hypertension. However, the results of such investigations should be interpreted with caution because a pressor effect has also been obtained with extracts of normal kidneys^{118, 119} and with extracts of various

FIGURE 8 Dog 2-60 Male 16.6 Kg

● = Mean blood pressure mm Hg ○ = Blood urea nitrogen mg/100 cc plasma
 AVC = Both main renal arteries and veins occluded The blood pressure did not become elevated D = Died

other normal organs¹²⁰. The existence of a pressor substance in the systemic or renal vein blood of animals with hypertension due to renal ischemia has not been demonstrated¹² and no greater quantity of pressor substance than the normal has been found¹² in the extract of plasma of dogs with this type of experimental hypertension. It has not been proved that the systemic

blood, spinal fluid, or urine of human beings with hypertension of any type invariably contains a pressor substance. Many reports of the finding of a pressor substance⁷⁰⁻¹⁰⁴ and of the failure to find a pressor substance¹⁰⁵⁻¹¹⁷ have been published. A discussion of these results would serve no useful purpose here. The pitfalls of such investigations were well shown by O'Connor¹²⁶. The burden of the proof still rests with those who claim the

FIGURE 9 Dog 2-61 Female 148 Kg

● = Mean blood pressure mm Hg ○ = Blood urea nitrogen mg per 100 c.c. plasma
 AVC = Both main renal arteries and veins occluded The blood pressure did not become elevated D = Died

invariable presence of an unusual amount of a known pressor hormone or of a new kind of pressor substance in pure or extracted blood, spinal fluid or urine of human beings with hypertension, especially the so-called benign or essential type. The experiments which follow are part of an investigation

that is being carried out to determine the part played by a possible humoral mechanism in the pathogenesis of hypertension due to renal ischemia

Constriction or Occlusion of Both Main Renal Arteries with Simultaneous Occlusion of Both Main Renal Veins One obvious but indirect way of testing for a possible humoral mechanism originating in the kidney is to constrict or occlude the main renal arteries, procedures which are now known to produce hypertension, and, at the same time, to occlude the main

FIGURE 10 Dog 2-95 Female 16.4 Kg

● = Mean blood pressure mm Hg ○ = Blood urea nitrogen mg per 100 cc RLVC = Both main renal veins occluded RLK = Both main renal arteries severely constricted
The animal died in uremia but the blood pressure did not become significantly elevated

renal veins in order to prevent the hypothetical effective substance from leaving the kidneys. Failure of development of hypertension would be evidence in favor of a humoral mechanism originating in the kidney as the cause of the hypertension.

In two dogs (2-60 and 2-61) the main renal arteries and veins of both kidneys were occluded at one time. The blood pressure and some of the

chemical changes in the blood of these dogs are illustrated in figures 8 and 9. Both developed severe uremia but no rise of blood pressure occurred during the short period of survival. These results are in keeping with those of Cash²⁷ who found that no elevation of blood pressure occurred in dogs after the permanent occlusion of both main renal arteries, veins and ureters.

In two dogs (2-51 and 2-95) the main renal veins were occluded and the main renal arteries were only severely constricted. The animals developed severe uremia but no elevation of blood pressure occurred during the short period of survival. Figure 10 illustrates the blood pressure and chemical changes in the blood of one of these animals, Dog 2-95.

Since it has been shown that the permanent constriction or occlusion of the main renal arteries alone is followed by a definite rise of blood pressure, these results may be interpreted as indicating the probable interference with the entrance of the hypothetical effective substance into the systemic circulation by way of the renal veins.

III. PART PLAYED BY ENDOCRINE ORGANS IN THE ORIGIN OF HYPERTENSION DUE TO RENAL ISCHEMIA

As part of the study of the humoral mechanism, an attempt has been made to investigate the part played by the endocrine organs that are known to produce a vaso-pressor hormone.

Hypophysis. Page²⁸ has shown that in dogs, hypophysectomy does not prevent the development of experimental hypertension due to renal ischemia, but that it does reduce the blood pressure in some animals with this type of hypertension. The significance of these contradictory findings cannot be evaluated at the present time. More experiments of this kind should be performed. The effect on this type of hypertension of removal of the various portions of the pituitary body have not yet been investigated.

Adrenals. In a previous communication² an experiment on Dog No. 8-9 was described in which excision of the right adrenal, the destruction of the medulla of the left adrenal, denervation of this adrenal and section of the left splanchnic nerves in the abdomen did not prevent the development of hypertension after the renal arteries were moderately constricted. The only conclusion that can be drawn from this experiment is that hypertension can develop in the absence of the medulla of both adrenal glands, as a consequence of renal ischemia, and that the presence of the medulla of the adrenal is not necessary for the development of this type of hypertension. Since then other experiments have been performed which were designed to determine the part which the cortex of the adrenal gland may play in the development of experimental hypertension due to renal ischemia. This is in the nature of a preliminary communication on this subject. The study is being continued and full details, including chemical studies, will be published later in collaboration with Dr. R. F. Hanzal. Up to the present time the following experiments have been performed.

Bilateral Adrenalectomy, without Supportive or Substitution Therapy and Renal Ischemia In this group of animals no supportive (sodium chloride and sodium bicarbonate or sodium citrate by mouth) or substitution (intra-venous cortical extract *) therapy was given after the removal of both adrenals

FIGURE 11 Dog 2-56 Female 232 Kg

● = Mean blood pressure, mm Hg ○ = Blood urea nitrogen mg per 100 cc of plasma ○ = CO₂ combining power, volumes per 100 cc RNA = Right adrenalectomy and right nephrectomy If anything, a slight elevation of blood pressure occurred after these procedures LKA = Left adrenalectomy and left main renal artery severely constricted The animal developed uremia and the blood pressure fell D = The animal died in uremia

In three dogs, both main renal arteries were permanently constricted at the time of the second adrenalectomy In two of these (2-56 and 2-62) the first adrenalectomy preceded the second by about two weeks, but in one animal the adrenalectomy and the constriction of both main renal arteries were carried out at the same time (Dog 3-22) The blood pressure did not become elevated in any of these animals, but the period of survival was short (Figure 11)

* The cortical extract used in these experiments was Eschatin which was generously supplied by Parke, Davis and Co

In one dog (2-64, figure 12) one adrenal was first removed and the main artery of the kidney on this side was constricted 12 days later. The blood pressure rose significantly, showing the responsiveness of the blood pressure of this animal. At the height of elevation of the blood pressure, the second adrenal was excised and the main renal artery of the corresponding side was permanently constricted. Instead of rising to a higher level, or at least remaining elevated, the blood pressure soon fell to a level below the previous normal for this animal and it died in 11 days of acute adrenal insufficiency.

In one dog (2-89 figure 13), the constriction of the main renal artery was carried out on the same side and at the same time as the first adrenalectomy. After this the blood pressure became significantly elevated which demonstrated the responsiveness of the blood pressure of this animal to the effect of renal ischemia. At the end of four weeks, while the blood pressure was still elevated, the second adrenalectomy was removed and the main artery of the kidney on the same side was constricted. Supportive treatment in the form of sodium chloride alone was given by stomach tube during the first 10 days and then sodium bicarbonate was added. After the second adrenalectomy and constriction of both main renal arteries, instead of rising to a higher level, the blood pressure gradually fell to a level below the normal for this animal and death occurred in 19 days.

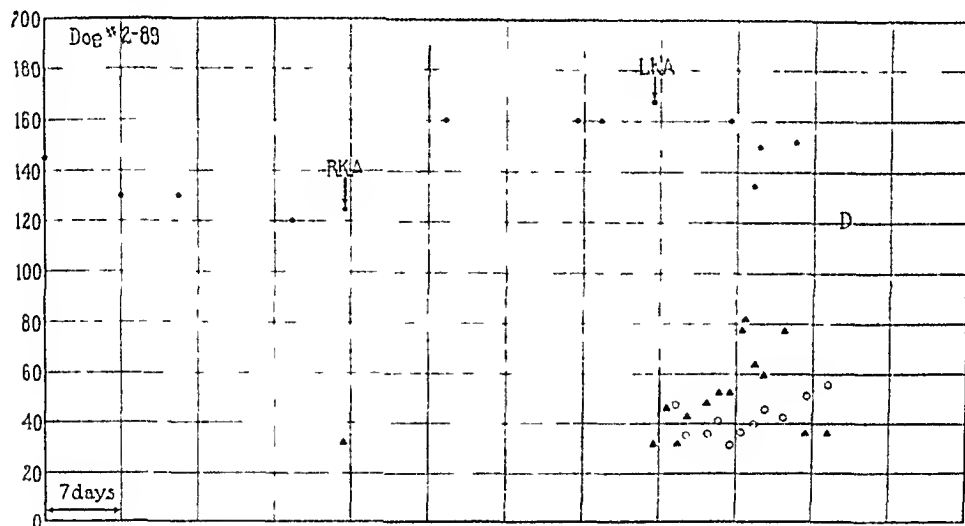

FIGURE 13 Dog 2-89 Male 17.6 Kg

● = Mean blood pressure mm Hg ○ = CO combining power volumes per 100 c.c. plasma ▲ = Non-protein nitrogen mg per 100 c.c. plasma RKA = Right adrenalectomy and right main renal artery moderately constricted. After this the blood pressure showed a moderate elevation. LKA = Left adrenalectomy and left main renal artery moderately constricted. From the time of the second adrenalectomy this animal received sodium chloride (0.75 gm per kg of body weight) by stomach tube for 9 days and from then on received in addition sodium bicarbonate (0.25 gm per kg of body weight). There was no greater elevation of blood pressure following the clamping of the second renal artery and the blood pressure gradually fell to below the original level. D = The animal died of acute adrenal insufficiency.

In another dog (2-81) the constriction of both main renal arteries was carried out at the same time as the bilateral adrenalectomy. This was followed by the administration of supportive treatment in the form of sodium chloride and sodium citrate by mouth. The animal survived 15 days but the blood pressure did not become elevated during that period. It fell gradually to a low level and the animal died of acute adrenal insufficiency.

The most convincing proof that in bilaterally adrenalectomized animals supportive treatment alone is not sufficient to permit elevation of blood

pressure or maintenance of elevated blood pressure due to renal ischemia was furnished by four dogs 2-77, 2-87, 2-88 and 3-08 (figures 14 to 17). These animals received both supportive and substitution therapy after the second adrenalectomy but after a varying length of time the administration of cortical extract was discontinued for varying periods. As a result, some of the animals received only supportive treatment in the form of sodium chloride and sodium bicarbonate or sodium citrate by stomach tube for as long as six weeks. In some of these animals the blood pressure remained at the normal or elevated level for a while, but invariably the blood pressure fell to a lower level and rose again to the normal level or higher only when the administration of cortical extract was resumed. These results show that bilateral adrenalectomy, even if followed by supportive treatment, interferes with the development and maintenance of the hypertension which is usually produced by renal ischemia.

FIGURE 14 Dog 2-77 Female 11.4 Kg

● = Mean blood pressure mm Hg ▲ = Non-protein nitrogen, mg per 100 cc ○ = () combining power, volumes per 100 cc RLKA = Bilateral adrenalectomy and both main renal arteries moderately constricted LN = Left nephrectomy + = Intravenous adrenal cortical extract begun — = Adrenal cortical extract discontinued. During the entire period following the bilateral adrenalectomy the animal received by stomach tube in two equal doses (9:00 a.m. and 4:00 p.m.) a total of 0.75 gm per kg of body weight of sodium chloride and 0.25 gm per kg of body weight of sodium bicarbonate. At no time during the four months of survival did the animal show elevated blood pressure. Several times when cortical extract was discontinued, the blood pressure fell to very low levels. K = Killed.

Bilateral Adrenalectomy with Supportive and Substitution Treatment and Renal Ischemia In Dog 2-77 both adrenals were excised and at the same time both main renal arteries were permanently constricted (RLKA in figure 14). During the entire four months of survival following these operations the animal received supportive treatment daily in the form of sodium chloride and sodium bicarbonate by stomach tube and intermittent substitution treatment in the form of intravenous cortical extract. Im-

mediately after the operation the administration of adrenal cortical extract was begun (+, figure 14) At intervals, for varying periods, the administration of cortical extract was discontinued The blood pressure remained at about the normal level during the periods when the cortical extract was also being administered When the cortical extract was discontinued (—, figure 14) the mean blood pressure gradually fell to a low level When the administration of cortical extract was resumed, the blood pressure rose again but never above the normal level This was repeated several times with the same result At no time was the pressure in this animal above normal

FIGURE 15 Dog 2-87 Female 128 Kg

● = Mean blood pressure, mm Hg ○ = CO₂ combining power, volumes per 100 cc
▲ = Non-protein nitrogen, mg per 100 cc + = Intravenous adrenal cortical extract begun
— = Intravenous adrenal cortical extract discontinued

Sodium chloride (0.75 mg per kg of body weight) and sodium bicarbonate (0.25 gm per kg body weight) were given during the entire period following the second adrenalectomy RKA = Right adrenalectomy and right main renal artery moderately constricted The blood pressure rose moderately LKA = Left adrenalectomy and left main renal artery severely constricted From this time the blood pressure gradually fell to a low level despite the supportive and substitution therapy D = Died

In dog 2-87 (figure 15) unilateral adrenalectomy and constriction of the main renal artery on the same side were first carried out After this first operation no supportive or substitution therapy was given Definite though slight elevation of blood pressure followed this procedure, which demonstrated the responsiveness of the blood pressure of this animal to renal ischemia After the second adrenalectomy and constriction of the corresponding main renal artery, both of which were performed at the

same time, about two weeks after the first adrenalectomy, supportive and substitution treatment were begun. The blood pressure remained elevated for a while but it did not rise to a higher level and, despite the treatment, gradually fell to below the previous normal.

In two dogs (2-88 and 3-08), one adrenal and the kidney on the same side were first removed. After an interval, the second adrenal was removed and the main artery of the only remaining kidney was constricted. During the entire period after the second adrenalectomy, these animals were given supportive treatment in the form of sodium chloride and sodium citrate by stomach tube. Immediately after the second adrenalectomy the administration of intravenous adrenal cortical extract was also begun. At intervals, for varying periods, the administration of cortical extract was

FIGURE 16 Dog 2-88 Female 168 Kg

● = Mean blood pressure, mm Hg ▲ = Blood non-protein nitrogen mg per 100 cc of plasma ○ = CO₂ combining power of blood, volumes per 100 cc of plasma RNA = Right nephrectomy and adrenalectomy LA = Left adrenalectomy LK = Left main renal artery moderately constricted + = Intravenous adrenal cortical extract begun — = Intravenous adrenal cortical extract discontinued

After the left main artery was constricted (LK) the blood pressure gradually fell to a very low level despite the intravenous adrenal cortical extract which was given for long periods at a time and the sodium chloride and sodium citrate which were given by stomach tube twice daily during the entire period following the second adrenalectomy. D = Died

discontinued. In dog 2-88 (figure 16), the main artery of the only remaining kidney was constricted about two weeks after the second adrenalectomy. There was no elevation of mean blood pressure following this procedure but instead the blood pressure fell gradually to a low level despite supportive and substitution therapy. When the cortical extract was discontinued, the blood pressure fell to even a lower level. The animal survived the second adrenalectomy about 12 weeks. During the intervals when cortical extract was discontinued, the mean blood pressure fell to unusually

low levels and rose again, but not even to the original level, when cortical extract was resumed. In the other dog, 3-08 (figure 17) the constriction of the main artery of the remaining kidney was carried out at the time of the second adrenalectomy. Definite elevation of mean blood pressure followed for a period of about one month. During this entire time intravenous adrenal cortical extract was given daily in addition to the salt and

FIGURE 17 Dog 3-08 Female 90 Kg

● = Mean blood pressure, mm Hg. Determinations made in a.m. □ = Mean blood pressure, mm Hg. LKA = Left adrenalectomy and left main renal artery severely constricted. + = Intravenous cortical extract begun. — = Intravenous cortical extract discontinued.

Sodium chloride and sodium citrate by stomach tube were given daily during the entire period after the second adrenalectomy.

The blood pressure became moderately elevated and remained elevated for one month during which the dog received substitution as well as supportive treatment. Whenever the intravenous cortical extract was discontinued (—) the blood pressure gradually fell to a level below normal. When cortical extract was begun again (+) the blood pressure gradually rose but did not reach the previous hypertensive level. D = Died of pneumonia.

sodium citrate by stomach tube. When the cortical extract was discontinued at the end of one month, the blood pressure gradually fell to a lower level. When the administration of cortical extract was resumed the blood pressure again became slightly elevated. The animal was accidentally exposed to cold and died of pneumonia.

Up to the present time, definite elevation of blood pressure due to renal ischemia has occurred in one other bilaterally adrenalectomized animal (Dog 2-96) that received substitution and supportive treatment. This animal survived the second adrenalectomy only 19 days. After the constriction of one main renal artery, which was performed eight days after the second adrenalectomy, there was a definite elevation of the blood pressure. Six days later, while the blood pressure was still elevated the main artery of the other kidney was constricted but the animal died the next day.

These results show that, even in the absence of both adrenals, provided adequate substitution and supportive treatment are given some dogs do develop a significant but not great elevation of blood pressure due to renal ischemia. Without substitution treatment such animals do not develop or maintain hypertension due to renal ischemia.

Renal Ischemia in Dogs with No Adrenal Medulla and Only a Small Remnant of Adrenal Cortex. Additional evidence that adrenal cortical hormone is necessary for the development of hypertension due to renal ischemia is provided by the following experiments.

In one dog (3-12 figure 18) approximately three-fifths of one adrenal was excised and the medulla of the remaining portion removed by means of a curette. At this operation the kidney on the same side was removed. At the second operation carried out 19 days later the other adrenal was excised, and the main artery of the only remaining kidney was constricted. In a second dog (3-16 figure 19) exactly the same procedure was carried out but this animal was left with about three-fifths of the cortex alone of one adrenal. There was an interval of 33 days between the two adrenal operations. For a few days following the removal of the second adrenal and constriction of the main renal artery of the only kidney both dogs received supportive treatment in the form of sodium chloride and sodium citrate by stomach tube. No adrenal cortical extract was given at any time. The blood pressure rose promptly following the production of renal ischemia. Even when the supportive treatment was discontinued, the blood pressure remained elevated and in 3-16 rose to even a higher level.

These results are interpreted as indicating the preservation of the function of the small portion of adrenal cortex which was left. In both animals, without the aid of supportive or substitution treatment this small remnant of cortex was sufficient to permit elevation of blood pressure due to renal ischemia. This is additional evidence in support of the view that the hormone of the cortex of the adrenal gland in some way plays a part in the pathogenesis of hypertension due to renal ischemia. More experiments are

being performed in order to elucidate the manner in which this hormone, itself not a vasopressor substance, helps to bring about the pressor effect which follows the production of renal ischemia

FIGURE 18 Dog 3-12 Female 11.4 Kg

● = Mean blood pressure, mm Hg LNPA = Left nephrectomy and partial adrenalectomy. The medulla was destroyed. About two-fifths of the cortex was left. RKA = Right adrenalectomy and right main renal artery severely constricted. * = Sodium chloride (0.75 gm per kg of body weight) and sodium citrate (0.25 gm per kg of body weight) were given by stomach tube from this time on. ** = Sodium chloride and sodium citrate discontinued. No cortical extract was given at any time. The blood pressure rose moderately following the constriction of the renal artery and remained elevated when supportive treatment was discontinued. D = Died.

SUMMARY

The results of the experiments that have been performed up to the present time on the pathogenesis of hypertension due to renal ischemia indicate that the mechanism of the development of this type of hypertension is primarily a humoral one of renal origin.

The failure of the various surgical procedures carried out on the nervous system to affect this type of experimental hypertension is evidently due to the persistence of the renal ischemia which cannot be altered by these procedures as long as the clamps remain applied. These experiments do not in any way controvert the results that have been obtained by the same procedures in the treatment of hypertension in man. They do emphasize, however, the importance of the reduced blood flow to the functioning

components of the kidney as the primary cause of this type of experimental hypertension and perhaps of human hypertension that is associated with arteriolar disease of the kidneys. Since the reduced blood flow in the human kidney is frequently due to narrowing of the arterioles alone, without narrowing of the large arteries, improvement of the circulation

FIGURE 19 Dog 3-16 Female 140 Kg

● = Mean blood pressure, mm Hg ▲ = Non-protein nitrogen, mg per 100 cc plasma LNPA = Left nephrectomy and partial adrenalectomy. The medulla was destroyed. About two-fifths of the cortex was left. RKA = Right adrenalectomy and right main renal artery severely constricted. * = Sodium chloride (0.75 gm per kg of body weight) and sodium citrate (0.25 gm per kg of body weight) were given by stomach tube from this time on. ** = Sodium chloride and sodium citrate discontinued. The animal is still living.

may result from these procedures on the nervous system due to relaxation of the arterioles in which the organic changes are not fixed. The beneficial effects reported in about the same percentage of cases of hypertension by surgeons using various procedures affecting the vasomotor nervous mechanism in the abdomen may therefore all be due to one cause, the improvement of the circulation through the kidney and not, as has been suggested by some, to the effect on the vasomotor mechanism of a large part of the vascular bed in the abdomen. The latter view has no support in these experiments. Whether or not improved circulation through the kidney is

responsible for the effect should be put to the test by a large series of renal denervations alone in cases of human hypertension. If improvement of the circulation through the kidneys be the common basis of improvement as a result of all of the various surgical procedures that have been carried out then denervation of the kidneys alone, if it can be accomplished, should give improvement in about the same small percentage of cases of hypertension.

The view that in the pathogenesis of hypertension due to renal ischemia a humoral mechanism involving a hypothetical effective substance of renal origin plays a part of primary importance is based almost entirely upon indirect evidence. Bilateral nephrectomy is not followed by hypertension, yet varying degrees of constriction and even complete occlusion of both main renal arteries are followed by hypertension. This difference is attributed to the absence of a hypothetical effective renal substance when the kidneys are absent. Even when both renal arteries are occluded the hypothetical effective substance can still be formed and washed into the renal veins by the accessory circulation through the capsule. The constriction or occlusion of both main renal arteries when accompanied by occlusion of the main renal veins, is not followed by the development of hypertension. This is interpreted as being due to interference with the entrance of the hypothetical effective substance into the circulation. Release of the constriction of the renal arteries by unscrewing or removing the clamps, causes a prompt return of the blood pressure to normal. The release of the clamp on the main renal artery of only one of two ischemic kidneys is also followed by return of the blood pressure to normal, but it takes longer for the blood pressure to reach the normal than when both clamps are released. This is in keeping with the finding that the clamping of one main renal artery causes only a temporary rise of blood pressure for a varying period. Excision of the ischemic kidney at the height of the hypertension which follows constriction of one main renal artery is also followed by prompt return of the blood pressure to normal. These experiments indicate that if one or two normal kidneys could be transplanted into an animal with hypertension due to renal ischemia, the blood pressure would return to normal because the source of the effective renal substance would be eliminated. Such a study is being carried out at the present time in collaboration with Doctor J. R. Kahn and Doctor W. B. Wartman. Up to the present time the only direct evidence suggestive of the existence of an effective substance has been the demonstration by other investigators^{11, 13} of an increased amount of pressor substance in ischemic kidneys as compared with normal ones.

Various experiments that have been carried out on the effect of complete adrenalectomy, with and without supportive and substitution therapy, and the effect of a small remnant of adrenal cortex only on the prevention or maintenance of hypertension due to renal ischemia indicate that the medulla plays no part, but that the cortex of the adrenal gland may play an important part in the mechanism of development of this type of hypertension.

Complete bilateral adrenalectomy without supportive or substitution therapy interfered with the development of this type of hypertension. Even with supportive treatment, but without substitution therapy, the animals failed to develop or to maintain hypertension due to renal ischemia. In several bilaterally adrenalectomized animals, however, moderate hypertension did develop when adequate supportive and substitution therapy was given. Because of this and because an amount of cortex close to the minimum requisite for survival and even the absence of both adrenals if supplemented by the administration of cortical extract still permitted the development of hypertension due to renal ischemia, the rationale of partial adrenalectomy which has been proposed and practised¹²⁷⁻¹³³ for the treatment of hypertension is questionable to say the least, except in cases of suprarenal tumor¹³⁴⁻¹⁴⁰ with hypertension in which the improvement results from the removal of the tumor in the adrenal.

The exact way in which the adrenal cortical hormone acts in conjunction with the hypothetical effective renal substance in the development and maintenance of hypertension due to renal ischemia has not been elucidated. Although the cortical hormone is not by itself a vasopressor substance, yet it may prepare the arteriolar musculature for the action of the hypothetical effective renal substance, or the reverse may be the case. The two may even combine before exerting their synergistic effect on the arteriolar musculature or they may act in conjunction with other hormones. These various possibilities are now being investigated.

CONCLUSIONS

Persistent hypertension has been produced in animals (dog and monkey) by constricting the main renal arteries which reduces the blood flow to the functioning components of the kidneys (renal ischemia).

Hypertension without or with disturbance of renal function, resembling in this respect the benign and malignant types, respectively, in man, can be produced by varying the degree of constriction of the renal arteries.

The results of various experiments indicate that this type of experimental hypertension is due primarily to a humoral and not to a nervous mechanism initiated by the ischemia of the kidneys.

The nature of the effective substance responsible for inducing the hypertension has not yet been elucidated.

The present indication is that the adrenal cortical hormone plays a part in conjunction with the hypothetical effective substance of renal origin in the pathogenesis of hypertension due to constriction of the main renal arteries.

THE NATURE OF THE CARDIOVASCULAR DISTURBANCES IN NUTRITIONAL DEFICIENCY STATES (BERIBERI) *

By SOMA WEISS, M.D. F.A.C.P., and ROBERT W. WILKINS, M.D.
Boston, Massachusetts

DURING the past half century significant advances have been made in our knowledge of the etiology of valvular heart disease. Likewise the recognition of the rôle of arterial hypertension, coronary disease, rheumatic myocarditis, adhesive pericarditis, hyperthyroidism, diphtheria and other infectious diseases has enabled clinicians to account for the majority of instances of non-valvular myocardial disease. There remain, nevertheless, a considerable number of patients who present manifestations of myocardial failure without valvular disease or any recognized type of myocardial disease. We have been prone to diagnose such obscure cases as "arteriosclerotic," "coronary" or "hypertensive" heart disease. A rigid scrutiny of evidence, however, including postmortem examination, often fails to corroborate the clinical diagnosis. Hence they remain "idiopathic." These obscure instances of myocardial failure probably include a number of diseases of varied etiology, as yet unrecognized. It is the purpose of this presentation to describe one type of cardiovascular dysfunction heretofore generally unrecognized in this country in which nutritional factors play a causative rôle.

It has been suggested by Shattuck,¹ Wechsler,² Minot, Strauss and Cobb and others that in certain types of polyneuritis a nutritional deficiency and particularly deficiency of vitamin B (B_1) plays an etiological rôle. These studies, however, raised the following question: If alcoholic polyneuritis, polynucuitis of pregnancy and certain other neuritides are related to nutritional deficiencies, and particularly deficiency of vitamin B_1 , why are they not associated with other manifestations, namely cardiovascular dysfunction such as occurs in patients with beriberi in other parts of the world? Soon after this question was raised we encountered in our wards two patients with nutritional deficiency polyneuritis, who suffered in addition from a severe degree of "idiopathic" circulatory failure. We therefore undertook a study of (a) the clinical characteristics of this condition, (b) the

* Presented in part before the St. Louis meeting of the American College of Physicians, April 19, 1937.

This investigation was aided by grants from the Proctor Fund of Harvard University for the Study of Chronic Disease and the Josiah Macy, Jr. Foundation.

physiological, chemical and morphological changes, (c) the etiology, and (d) therapeutic measures. A summary of the first part of this investigation was presented before the 1936 meeting of the Association of American Physicians.⁴

MATERIAL AND METHOD OF STUDY

In order to determine whether the disease exists as a clinical problem, we undertook an analysis of the records of some 900 patients suffering from various types of nutritional deficiency, including general malnutrition, chronic alcoholism with or without polyneuritis, pellagra, neuritis of pregnancy and diabetes. In this group we discovered 85 cases in which cardiovascular dysfunction of varying severity could not be ascribed to the usual etiological factors. Because all instances in which organic lesions of the cardiovascular system existed were eliminated and because many of the cases were observed by physicians not experienced in cardiovascular problems, the number selected must be considered as minimal. This conclusion is corroborated by the fact that within a period of two years we have personally studied 35 patients from a total of 5,506 admissions to two general medical services in this hospital. The observations here presented are therefore based on a total group of 120 cases.

OBSERVATIONS

Nature and Pathogenesis of Cardiovascular Dysfunctions

Age and Sex Incidence The ages of the 120 patients varied between 24 and 67 years, 84 per cent fell in the age group 30 to 59 years. Eighty-two per cent were males and 18 per cent females. This age and sex incidence can, however, be considered but an approximation, since the majority of the cases have been gathered from available records and numerous elderly patients were eliminated because of the simultaneous presence of hypertension or arteriosclerosis.

Nutritional History The majority of the patients were heavy consumers of alcohol. A smaller group gave a history of unbalanced diet as a result of psychic peculiarities ("food cranks"), of drug addiction or medical restriction of diet or of persistent nausea, such as is present in pregnancy. In relatively few patients poverty played a rôle. The caloric intake was adequate or more than adequate in the majority, as was also indicated by their weight. Reliable detailed history was obtainable in only a small group. The estimated vitamin B (B_1) intake in this group was less than that indicated by Cowgill as liable to produce polyneuritis. There were a few patients, on the other hand, in whom both the caloric and the estimated vitamin B (B_1) intake were adequate. In this group there were usually indications of digestive dysfunction suggesting lack of proper absorption or utilization of the essential food substances.

Symptoms and Signs of Non-Cardiovascular Origin Cardiovascular

abnormalities were present in the majority of instances, along with other recognized manifestations of nutritional deficiency and particularly with those of "beriberi" and pellagra. In a smaller group scurvy was present. In some instances, however, circulatory failure was the sole manifestation. Table 1 shows the associated signs not referable to the cardiovascular system. In a given patient one or more of these signs were present in various combinations, but peripheral neuritis, gastrointestinal disturbances and psychosis were most frequent.

TABLE I
Non-Circulatory Manifestations

| | |
|---------------------|------------------|
| Peripheral neuritis | Hypoproteinemina |
| Psychosis | Optic neuritis |
| Glossitis | Dysphagia |
| Constipation | Hoarseness |
| Diarrhea | Aphonia |
| Dermatitis | "Spoonied" nails |
| Anemia | Purpura |

Symptoms and Signs Referable to the Cardiovascular System The clinical symptoms and signs referable to the cardiovascular system are presented in table 2. The most frequent combinations of symptoms and signs

TABLE II
Circulatory Manifestations

| <i>Symptoms</i> | |
|------------------------------|-----------------------------|
| Tachycardia with palpitation | Prominent cardiac pulsation |
| Fatigability | Pulmonary rales |
| Dyspnea on exertion | Engorged veins |
| Cough | Gallop rhythm |
| Edema | Warm extremities |
| Orthopnea | "Pistol" sounds |
| Paroxysmal dyspnea | Dilated heart |
| | Cyanosis |
| <i>Signs</i> | Syncope |
| Tachycardia | Circulatory collapse |
| Embryocardia | Bronchopneumonia |
| Systolic murmurs | Diastolic murmurs |

were dyspnea on exertion with tachycardia and embryocardia, palpitation with gallop rhythm, prominent cardiac and epigastric pulsations, bounding peripheral pulses with sounds ("pistol shots"), particularly over the carotid, subclavian and femoral arteries, and edema, both diffuse and dependent, with distended veins. The skin was often flushed and warm. In 24 patients selected for special study, the cardiovascular disturbance was severe and, at times, extreme.

The *heart* was normal in size or enlarged. There was usually a prominent precordial pulsation with a rapid systolic rise and diastolic fall. At times the extensive thoracic pulsations over the heart suggested cardiac enlargement, but this was not always corroborated by roentgenological examination. The heart rate was usually rapid. Under rest and dietary

treatment the tachycardia returned to the normal level, either slowly or rapidly. In the latter case transient bradycardia frequently followed.

The character of *dyspnea* varied considerably. In the majority of patients dyspnea occurred only on slight or moderate exertion. In some, continuous dyspnea and orthopnea developed. Several patients without evidence of pulmonary infection complained of an irritating, dry "hacking" cough, particularly annoying at night. Patients with typical attacks of cardiac asthma (paroxysmal dyspnea) were also encountered. In some instances attacks of dyspnea appeared with unexpected suddenness in patients who had been in vigorous health. Such attacks were also observed in bed-ridden patients. Signs of pulmonary congestion were frequently present, and cloudiness of the lung fields was seen on roentgenological examination. Patients with severe polyneuritis were less liable to have advanced failure of the circulation. The most plausible explanation for the infrequent coexistence of the two conditions seems to be that the polyneuritis prevents muscular exertion.

The *arterial pressure* was usually normal with a tendency to increased pulse pressure. In some cases the systolic pressure was moderately elevated during the acute stage of circulatory failure, but it returned to normal when the patient's condition had improved. The *venous pressure* was elevated or normal.

Edema was present in one group of patients. In some it was of extreme degree and diffuse, in others only dependent in type. Often at the time of admission the severity and extent of edema were not appreciated. A patient with full, round facies and robust appearance rapidly changed to a thin-faced individual with a delicate bodily structure. Decreases in the osmotic pressure of the blood, even when present, could not be held responsible because the edema often disappeared while the osmotic pressure remained essentially unchanged. The protein content of the edema fluid was low (Cases 1, 2 and 4).

Attacks of *syncope* were observed in five patients. The attacks were associated with asystole and fall in the arterial pressure, and they could be induced by stimulation of the carotid sinus. The hyperactive carotid sinus reflex in these patients was of the vagotonic type. Following the administration of a diet rich in vitamin B (B_1), the irritable state of the carotid sinus reflex subsided and in four cases stimulation of the sinus subsequently produced no symptoms and no asystole. The fifth patient developed an acute psychosis and was transferred to another institution.

Circulatory collapse developed in some of the patients with congestive failure of the circulation. In other instances in which it occurred the only premonitory sign was tachycardia.

Patients with severe congestive failure of the circulation were especially prone to develop *fever*. The condition of these patients often became much more serious with the onset of an elevated temperature. In some cases the

fever seemed to have precipitated the congestive failure. It is equally plausible, however, that the reverse was true. Signs of bronchopneumonia were often detected, but sometimes the cause of fever remained obscure even after postmortem examination.

Electrocardiographic Studies. Electrocardiograms taken in 67 cases with normal blood pressures and with no clinical evidence of organic heart disease disclosed abnormalities in all but five cases (table 3). Figures 8

TABLE III
Electrocardiographic Findings in 67 Cases

| | No. of Cases | % of Total |
|--|--------------|------------|
| Normal records | 5 | 7 |
| Abnormal records | 62 | 93 |
| Change in direction of T-wave | 46 | 68 |
| Sinus tachycardia (100 or over) | 42 | 63 |
| Prolonged Q-T (electrical systole) | | |
| Above Echer-Li standards (Upper limit of K-Miles 0.38 females 0.42) | 53 | 79 |
| Above Shipley-Hillman standards (Upper limit of K-Miles 0.43 females 0.45) | 30 | 45 |
| Ventricular premature beats | 10 | 15 |
| Auricular premature beats | 9 | 13 |
| Low voltage of QRS (below 5 mm.) | 6 | 9 |
| Auricular fibrillation | 3 | 4 |
| Intraventricular block | 3 | 4 |

11, 12, and 15 are examples of the electrocardiographic changes observed. These changes occurred in patients with nutritional deficiency or with clinical polyneuritis, pellagra, psychosis, or combinations of these syndromes. In some instances no other clinical manifestations of deficiency disease existed. Not all patients with the same type of nutritional deficiency had changes in the electrocardiograms; nor were they present in all instances of polyneuritis or pellagra. No explanation can be offered for their absence in patients with apparently the same underlying disease. The electrocardiographic changes disappeared with improvement after the administration of a diet rich in vitamin B or of crystalline vitamin B₁. Patients were also observed in whom the abnormality of the electrocardiogram appeared or became accentuated immediately after administration of vitamin B₁ or of food rich in vitamin B (B₁), only to disappear eventually.

Hemodynamics of the Circulation. In 13 patients technical measurements of the circulation were made. The velocity of the blood flow, the oxygen difference of the blood in the femoral artery and vein, the vital capacity of the lungs and the venous pressure in the antecubital and femoral veins were usually measured on several occasions. The most significant finding was that patients with enlarged heart, rapid heart rate, gallop rhythm, dyspnea, orthopnea, generalized edema, low vital capacity and elevated venous pressure had a normal or increased velocity of blood flow and a low arteriovenous oxygen difference. Such behavior of the circulation differs from that in other types of organic heart disease in which there

generally exists a direct relationship between the degree of congestive failure and the slowing of the blood flow^{5,6}

The rapid blood flow confirmed the clinical impression created by the warm extremities, the flushed color, the bounding pulses and the increased arterial pulse pressure namely, that there was a *generalized arteriolar dilatation*. This is an important factor in the clinical picture. Indeed after treatment with vitamin B₁ one of the most constant and dramatic effects was the slowing of the circulation to a normal or temporarily even to a sub-normal level. The beneficial effect in lowering peripheral capillary pressure and thereby enhancing the removal of edema fluid by the venules was demonstrated in several patients who had diuresis following this slowing while the osmotic pressure of the blood and the venous pressure remained unchanged (Cases 2, 3 and 4). Arteriolar constriction following B₁ therapy must also react, in turn, centrally on the heart in the same beneficial manner as the closing of an arteriovenous aneurysm.

With improvement after vitamin B₁ therapy the heart rate slows, the gallop rhythm subsides and the size of the heart returns to normal. The elevated venous pressure falls, the vital capacity increases and the edema, orthopnea and dyspnea disappear. A simultaneous study of the heart, peripheral vascular system and circulation indicates that the failure of the circulation in patients with nutritional deficiency depends on the combined effects of dilatation of the peripheral arteriolar system and myocardial failure.

While some of the patients exhibited the syndrome of pure *right ventricular failure*, this was not the characteristic manifestation. There were generally symptoms and signs of *left ventricular failure* as well. Moreover patients with only pulmonary congestion and edema, exhibiting attacks of paroxysmal dyspnea, were also observed. In some patients rapidly developing *circulatory collapse* or shock dominated the clinical picture. Our observations therefore fail to reveal a rigid circulatory syndrome. In general the clinical picture in patients with a severe degree of circulatory failure was characterized by (a) good and often rapid peripheral circulation associated with warm skin, high bounding pulse with arterial sounds and normal or increased velocity of blood flow, (b) a failing heart with preponderant right or left ventricular failure, as indicated by high peripheral venous pressure and edema, or by dyspnea, orthopnea, paroxysmal attacks of dyspnea associated with low vital capacity, the physical signs of congestion, and cloudiness of the lung fields in the roentgenogram, (c) a tendency to terminal circulatory collapse or shock.

Chemical Changes. Analysis of the blood chemistry revealed the following trends: (1) Moderate lowering of serum proteins and colloid osmotic pressure, (2) normal or moderately increased non-protein nitrogen, (3) moderate elevation of fasting blood sugar, (4) normal carbon dioxide capacity, (5) increase in bisulphite binding substances⁸. The urine analyses showed tendency to ketosis, and occasional glycosuria.

Organic Heart Disease and Nutritional Deficiency

An especial attempt was made to study cardiac and circulatory disturbances in relation to nutritional deficiencies in their pure form. Whether nutritional factors play a rôle in patients with organic cardiovascular disease was not the main interest of the investigation. This problem is particularly difficult because of the two simultaneously existing major variables and because no objective index is available for measuring the specific relationship of circulatory failure to nutritional deficiency. We have encountered patients with hypertensive and chronic rheumatic heart disease, however, in whom a severe degree of congestive failure has been precipitated on repeated occasions by lack of proper food or by the consumption of large amounts of alcohol.

Frequency

The cardiovascular disturbances here described occurred in a ratio of about 1 in 160 admissions to the medical wards. A comparison of the occurrence of this type of cardiovascular dysfunction with the frequency of some of the other diseases of the cardiovascular system indicates that in this hospital the condition is more frequent than congenital heart disease, adhesive pericarditis, hyper- or hypothyroid heart disease and subacute bacterial endocarditis. The relative frequency of the condition, however, will vary considerably in different strata of society, in different races and in various parts of the country.

Prognosis

Under proper medical management the condition offers a good prognosis in the majority of instances. In the advanced stage, particularly if the deficiency has existed for a long time, the circulatory failure may terminate fatally in spite of treatment. Among the 35 cases personally observed, fatalities due to acute failure of the circulation occurred in four, two of which were untreated. In an additional five cases death was due primarily to other causes. The improvement may be rapid or slow. The determining factors in the rate of improvement have not been established, but the duration as well as the severity of the nutritional deficiency seems to be important. Final recovery is apparently complete in those patients who survive the acute failure.

Differential Diagnosis

The absence of the recognized etiological causes of organic heart disease, on the one hand, and the history of unbalanced diet or digestive dysfunction, on the other, should suggest the possibility that the cardiovascular disturbance is of nutritional origin. If certain non-circulatory manifestations of vitamin deficiency described above are also present, such a possibility is enhanced. The combined presence of congestive failure of the circulation and a relatively or absolutely increased rate of the circulation makes the

diagnosis probable The assured diagnosis depends on complete recovery of the patient in response to rest, and to diet or extracts rich in vitamin B₁. Some cases of obscure myocarditis may offer difficult differential diagnostic problems The history of unbalanced diet and of the peripheral vascular signs are of aid in such problems

Treatment

As in other types of heart disease, evaluation of the efficacy of therapeutic measures is difficult, mainly because of the inadequacy of control observations Patients with circulatory failure caused by nutritional deficiency kept at rest in bed, with or without digitalis, diuretics and other measures, usually showed a moderate degree of improvement In three cases, however, severe circulatory embarrassment with collapse indicated the possible harmful effects of such a control period In 25 patients observed during the past 12 months the usual method of study was as follows On entrance to the hospital the patient was kept in bed and was given a special diet deficient in "B" vitamins Usually no medication was given or occasionally digitalis and diuretics were administered in relatively large doses during a period of from four to seven days Frequent measurements of various functions of the circulation were made Following these control observations, all medication was discontinued and vitamin B₁ extract, or, more recently, crystalline vitamin B₁ was administered intravenously, intramuscularly or subcutaneously several times a day for from four to seven days* During this period the vitamin "B" deficient diet was continued and the measurements and clinical observations were repeated Subsequently the parenteral administration of vitamin B₁ was replaced by a diet and oral extracts rich in vitamin B₁ The dosage of crystalline vitamin B₁ varied In the early stage of our studies we used doses of 10 to 20 mg a day More recently we have given an average of 50 mg and as high as 130 mg a day Because there is but scant available information on the elimination and storage of vitamin B₁ in the human body, the dosage is necessarily empirical We have purposely administered considerably larger doses than those indicated by animal experiments"

In spite of the fluctuation of the state of the circulation during the control period, following the administration of extracts or crystals of vitamin B₁, as indicated by the illustrative cases, the improvement was frequently striking In general the improvement was most rapid in patients with a severe degree of congestive failure The first change observed was the increased utilization of oxygen and slowing of the blood flow, which occurred in eight cases in which measurements were made within 24 hours following the administration of the first dose of vitamin B₁ These initial

* Two preparations were used for parenteral administration a highly purified and standardized preparation of vitamin B₁, obtained through the courtesy of the Winthrop Chemical Company, Inc., New York, and crystalline vitamin B₁, obtained through the courtesy of Merck & Company, Inc., Rahway, New Jersey

changes in the circulation, accompanied by subjective improvement, were followed by a marked degree of diuresis, slowing of the heart rate and decrease in the venous pressure. Simultaneously there was a slow but steady rise in the vital capacity of the lungs and a decrease in cardiac size. The cardiovascular abnormalities last to disappear were those revealed by the electrocardiogram. No untoward symptoms were observed even after such a large intravenous dose of crystalline B_1 as 50 mg. In some patients a temporary elevation of the arterial pressure of several days' duration followed the first course of treatment.

Although our primary interest was the study of cardiovascular dysfunction in relation to nutritional deficiencies, we have had opportunity to observe the response of patients with *polyneuritis* to crystalline vitamin B_1 . There was no parallelism between the rate of improvement in the circulatory functions and in the nervous functions. The improvement usually was more striking, rapid and complete in the cardiovascular than in the neurological disturbances. The latter, particularly when chronic, in spite of the large doses of crystalline vitamin B_1 , returned only slowly and incompletely toward normal. In a few instances, on the other hand, particularly in the mild cases of short duration, improvement in vibration sense, paresthesias and motor function occurred within two days after treatment was instituted.

Effect of Crystalline Vitamin B_1 on the Non-Deficient Cardiovascular System

Seven patients with no vitamin deficiency were given parenteral crystalline vitamin B_1 in doses ranging from 10 to 120 mg. a day for from one to seven days. In no case was there significant change in any aspect of the heart or of the circulation. In two patients, shortly after injection there occurred temporary minor changes in the electrocardiograms. Four patients had edema on which the vitamin had no diuretic effect. Two patients with clinical signs of B_1 deficiency (*polyneuritis*) but without cardiovascular dysfunction showed no changes in the heart or circulation following large doses of crystalline B_1 . Two patients who initially had had vitamin deficiency and cardiovascular dysfunction of the type described, which returned to normal after the first course of B_1 , showed no effect when a second course of vitamin was given several weeks later (Cases 3 and 4).

Morphological Observations

Wenckebach¹⁰ has described microscopical changes in the hearts of patients with "beriberi heart" in Java, which he has claimed are characteristic, if not specific. We have therefore examined sections of the hearts of patients who died as a result of alcoholic and other types of nutritional *polyneuritis* or *pellagra*, with or without the type of cardiovascular disturbances described above. Of 30 cases 19 exhibited cardiovascular dysfunction in addition to tachycardia. Death in these cases was often the

result of sudden circulatory collapse, associated with terminal bronchopneumonia. The myocardial fibers and the conductive bundle of this group exhibited various degrees of "hydropic" degeneration. In addition, intercellular edema and collagen were present. Figures 1, 2, 3, 5, 6, and 7

FIG 1 "Hydropic" degeneration of muscle fibers of the heart with "interstitial edema" in pellagra and polyneuritis 400 X

demonstrate the types of changes observed. No relationship could be found between the degree of histological change and the clinical manifestations. In no instance was there evidence of inflammation.

The sections of the hearts of the group with nutritional deficiency and cardiac failure, as well as of cases with polyneuritis or pellagra without heart failure, have been compared with cardiac sections of two control groups. The first group consisted of eight cases of portal cirrhosis of the liver without manifestations of vitamin deficiency. The second group included 14 cases without heart disease and four cases with fatal organic heart disease. In both control groups there were cases with a moderate degree of "hydropic" degeneration and with interstitial edema similar to that found in the deficient group.

The size of the heart varied. In the majority of instances the weight of the heart was normal, and there was moderate dilatation of the right ventricle. In nine out of 30 cases there was an increase in weight and a considerable degree of dilatation of the cardiac chambers, particularly the right ventricle. In the group observed by us dilatation of the right ventricle

FIG. 2 "Hydropic" degeneration of cross sections of subendocardial conductive fibers in pellagra and polynneuritis. 200 X

was not as marked or as frequent as in the group of "beriberi hearts" studied by Wenckebach in Java.¹⁰ The histological changes, on the other hand, were identical with those described by Wenckebach. Our data, in contrast to those presented by Wenckebach, do not indicate that the histological changes observed are specific or even characteristic. They can be present in other diseases.

Sections of the brain revealed swelling of the ganglion cells with marginal displacement of cell nuclei within the vagus centers. In one case there was destruction of the cells with replacement by glia nodules (Dr. L. Alexander).

Water Content of Cardiac and Skeletal Muscles

Aalsmeer and Wenckebach¹¹ have suggested that deficiency of vitamin "B" produces physicochemical and physiological alterations in the body which lead to water retention in the cardiac and skeletal muscles. They

FIG 3 "Hydropic" degeneration of longitudinal section of subendocardial conductive fibers in pellagra and polyneuritis

have claimed that the "hydropic" degeneration and interstitial edema are indications of such changes. Wassermeyer¹² reported that the heart of birds deficient in vitamin B contains more water than that of normal animals.

In order to obtain information on this phase of the problem, we have measured the water content of the right and left ventricles and of the abdominal rectus muscle in the following conditions: (a) nutritional deficiencies with or without heart failure, (b) control group with no heart disease, (c) organic heart disease with anasarca.⁴ The water content was measured with a gravimetric method. The group with nutritional deficiencies included three patients with combined polyneuritis and pellagra, one

with scurvy and polyneuritis and five with nutritional deficiency, heart failure and cardiac dilatation. No significant difference in the water content of the heart in various groups was observed. It is of interest that even in the group with organic heart disease and with generalized anasarca and with low serum protein, the water content of the myocardium

FIG 4 The cardiac shadow in Case 1

remained essentially normal. The abdominal rectus muscle, on the other hand, showed at times increased water content in the presence of anasarca.

Case Reports Illustrating Types of Cardiovascular Disturbances and Therapeutic Responses Observed

The following cases are reported in detail as examples of the types of cardiovascular disturbances encountered and of the responses to the therapeutic agents administered. Additional cases have been reported in a previous communication.⁴

Case 1 *Severe congestive failure of the circulation, mild pellagra and polyneuritis, fatal circulatory collapse* R N, an odd-job man, aged 36 years, had been drinking $\frac{1}{2}$ pint of alcohol daily for two years, and one pint to one quart a day for three months. He had eaten a grossly inadequate diet which became more deficient the more he drank. He complained of increasing dyspnea on exertion for one month, dependent edema for three weeks, hacking cough for 10 days and orthopnea with insomnia for one day.

FIG 5 "Hydropic" degeneration of the muscle fibers in Case 1

The family history and past history were non-contributory.

Physical examination revealed a well-nourished, slightly jaundiced man with severe orthopnea and diffuse edema, more pronounced in the dependent parts. There was pigmentation and scaliness of the skin on the dorsum of the hands and feet and on the lower legs. The veins of the neck were engorged. The heart was percussed 12 cm to the left and 5 cm to the right of the midsternal line. A gallop was heard at the apex and a blowing systolic murmur at the base of the heart. The second sound at the pulmonic area was accentuated. The heart rate was 120 per minute and the rhythm was regular, arterial pressure 110 mm Hg systolic and 46 diastolic. "Pistol" sounds were audible over the carotid and femoral arteries. The lower third of both lungs posteriorly was dull to percussion, and over these areas and also anteriorly over the left hilar region moist râles were heard. The abdomen was pro-

tuberant and there was shifting dullness in the flanks. A firm liver edge was palpable 4 cm below the right costal margin. The spleen was not felt. Knee jerks were greatly diminished and ankle jerks were absent. Temperature 98° F. Respirations 36 per minute. Weight 183 pounds (usual weight 160 pounds).

FIG 6 Perivascular "edema" and separation of the muscle fibers in Case 1

Laboratory studies *Urine*, acid, specific gravity 1.025, albumin trace, sugar 0 bile positive, sediment, occasional leukocytes and hyaline casts. *Blood*, hemoglobin 87 per cent, erythrocytes 4,430,000 per cu mm. Icterus index 14. Total protein content of the plasma 5.2 gm per 100 cc, albumin 2.92 gm and globulin 2.28 gm, with calculated osmotic pressure 200 mm H₂O. The non-protein nitrogen of the plasma was 65.6 mg per 100 cc. The Hinton test was positive. The Takata-Ara test was negative. *Edema fluid* from the thigh contained total protein 1.50 gm per 100 cc, albumin 1.10 gm and globulin 0.40 gm.

A 7-foot roentgenogram of the heart confirmed the clinical measurements (figure 4). The electrocardiogram was interpreted as within normal limits except for tachycardia. Special circulatory studies showed the venous pressure in the femoral and cubital veins to be 27 cm H₂O, the circulation time 15.5 seconds, the femoral arteriovenous oxygen difference 0.75 volumes per cent, and the brachial arteriovenous oxygen difference 1.39 volumes per cent. The vital capacity was 2,500 cc.

While this patient obviously was suffering from severe circulatory failure with rapid blood flow, he was made fairly comfortable with small doses of morphia. It

was thought safe to withhold therapy until a control period had elapsed. There was subjective relief, but there were no changes in the edema or other signs of circulatory failure. On the third day the venous pressure had risen to 32 cm H₂O. It was then decided to give vitamin B₁, but before it could be administered the patient suddenly went into circulatory collapse, from which he died.

Postmortem examination revealed marked anasarca and mild jaundice of all tissues. The heart weighed 520 gm. The right auricle and ventricle showed marked dilatation and moderate hypertrophy, the left auricle and ventricle were normal. Except for the aortic cusps, at the bases of which were minimal atheromatous thicken-

FIG 7 Separation of the muscle fibers by edematous collagen in Case 1

ings, all valve cusps were thin, membranous and translucent. There was no evidence of rheumatic or luetic endocarditis. The coronary arteries, the epicardium and the pericardium were normal. The aorta showed minimal atheromatous change $\frac{1}{2}$ cm above the aortic valve, but otherwise was perfectly normal.

The right lung weighed 1,300 gm and the left 1,080 gm. The pleural surfaces were smooth and glistening, but purple in hue. There were slight depressed scars at each apex. The crepitation was markedly decreased, giving the lungs a "meaty" consistency. The cut surfaces were uniformly purplish-red throughout all lobes of both lungs. There was an extreme degree of edema and congestion, and large quantities of serosanguineous fluid could be easily expressed. In the base of the right lower lobe was one small area of minimal bronchopneumonic consolidation.

The liver weighed 2,480 gm. It was firm, the surface smooth, its capsule thin and of normal translucence. Its entire surface showed a marked "nutmeg" appearance. The kidneys, spleen and other abdominal viscera were markedly congested.

The brain weighed 1,560 gm. There was atrophy of both frontal lobes, most pronounced in the pre- and post-central gyri. There were several very small petechial hemorrhages in Ammon's horn. The spinal cord and peripheral nerves were normal in appearance. The rest of the gross examination was normal.

Microscopy revealed these additional findings. The right ventricle showed marked "edema" of the intermyocardial connective tissue, with separation of the muscle fibers. There was also "intracellular edema" of the myocardium (figures 5, 6, and 7). The left ventricle showed marked increase in the collagenous connective tissue of the epicardium. There was an increase in the interstitial tissue, especially that lying immediately beneath the epicardium. This connective tissue was extremely "edematous," causing separation of the myocardial cells.

The lungs showed marked dilatation and congestion of the capillaries of the alveolar walls. The alveoli contained many large macrophages filled with brown pigment, many extravasated erythrocytes and granular debris. In one area numerous polymorphonuclear leukocytes were present.

The liver showed extreme fatty degeneration. Many cells, especially in the centers of the lobules, were degenerated. There was no increase in connective tissue. No "alcoholic" hyaline was seen. The brain showed widespread perivascular hemorrhages and degenerative changes in numerous pyramidal cells.

Case 2 Congestive failure of the circulation, polyneuritis, Korsakoff's psychosis, improvement on vitamin B₁. W. E., an unemployed painter aged 50 years, was disoriented and confused and gave an unreliable history. He admitted taking one pint of pure alcohol daily for years and stated that he rarely ate anything. He was brought in by welfare workers from a cellar where he had been living for weeks, unable to move. He had no complaints.

Physical examination revealed an extremely weak, poorly nourished man with diffuse edema which involved the sternum and face. He lay flat in bed in no apparent distress. The skin of the face showed marked acne rosacea with crusted pustular lesions. The skin of the extremities was dry, scaly and very warm. There was a pustular conjunctivitis and a small white ulcerous plaque on the right cornea. The pupils were quite small and reacted sluggishly to light. The tongue was smooth on the edges. There was moderate engorgement of the veins of the neck. The heart was percussed 11 cm. to the left and 6 cm. to the right of the midsternal line. The sounds were of poor quality but there were no murmurs. The heart rate was 90 per minute and the rhythm was regular. The arterial pressure was 105 mm. Hg systolic and 75 diastolic. Sounds were audible over the carotid, femoral and brachial arteries. The lungs were resonant, but moist rales were heard over the lower third of both lungs posteriorly. In the abdomen the liver edge was felt 1 cm. below the right costal margin. There was bilateral wrist- and foot-drop. The biceps and triceps jerks were greatly diminished and the knee and ankle jerks were not obtainable. There was marked muscle and nerve tenderness in the legs. Sensory examination was unsatisfactory, but there was apparently hypesthesia of the lower legs. Temperature was 99° F. Respirations 25 per minute. Weight 158 pounds.

Laboratory studies. *Urine*, acid, specific gravity 1.012, albumin 2 plus, sugar 0, bile 0, acetone 0, diacetic acid 0, pyruvic acid 0, sediment, many leukocytes and hyaline casts. *Blood*, hemoglobin 74 per cent, erythrocytes 3,200,000 per cu. mm., leukocytes 9,150, neutrophils 78 per cent. The fasting blood sugar was 144.5 mg. per 100 c.c. and the non-protein nitrogen 98 mg. The total protein content of the plasma was 5.3 gm. per 100 c.c., albumin 3.0 gm., globulin 2.3 gm., with calculated osmotic pressure 207 mm. H₂O. The icterus index was 10. The Hinton test was negative. The Takata-

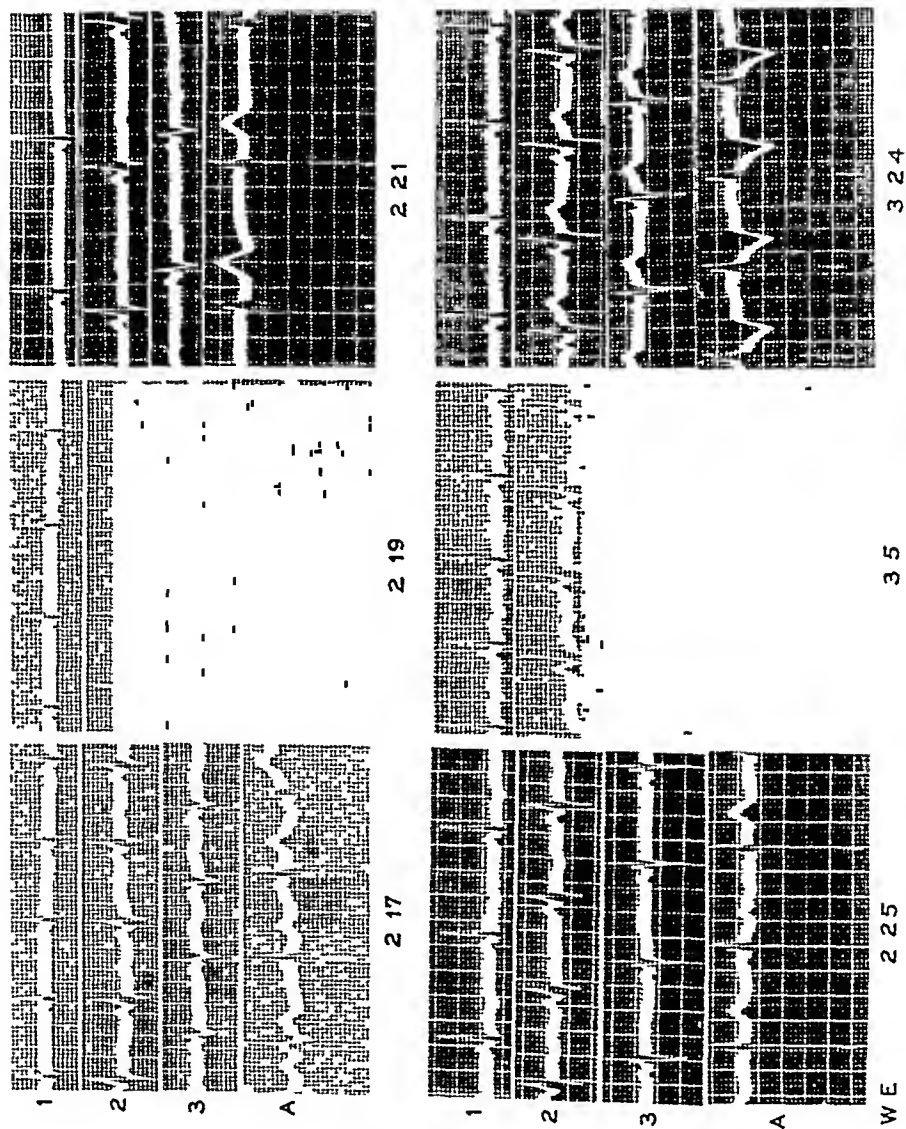

Fig 8 Electrocardiograms in Case 2 Note changes in amplitude and in T-waves

Aia test was positive. The bisulphite binding substances in the blood were 9.9 mg per 100 cc (as pyruvic acid). Edema fluid from the arms showed a total protein content of 1.2 gm per 100 cc, albumin 0.66 gm, globulin 0.55 gm. Lumbar puncture revealed a spinal fluid pressure of 200 mm H₂O, normal dynamics and a normal fluid.

Special circulatory studies showed vital capacity 1,700 cc, venous pressure 17 cm H₂O, circulation time 11 seconds and femoral arteriovenous oxygen difference 1.84 volumes per cent. The electrocardiogram (figure 8) showed low voltage (7 mv), abnormal T-waves and prolonged Q-T interval (K equals 0.47) interpreted as myocardial disease. The 7-foot roentgenogram confirmed the enlargement of the heart found clinically (figure 9).

FIG 9 The cardiac shadow in Case 2 before treatment

The patient was placed on a vitamin-free diet, fluids ad lib, no other therapy. His course is graphically shown in chart 1. On the second day it was found that he had retention of urine, necessitating constant drainage. On the fourth day he lapsed into coma and appeared moribund. There had been no essential change in any aspect of the circulation or blood chemistry. It was decided not to delay vitamin therapy. Accordingly, 30 mg of synthetic crystalline vitamin B₁ were administered intravenously. At that time the patient was in deep coma, had Kussmaul breathing, and extremely small pupils which did not react to light. One hour and a half after the injection there was a most remarkable change. The patient aroused, asked for water,

then took a large bowl of boiled milk and crackers. The breathing became normal, the pupils were dilated and reacted normally to light and on accommodation. Vitamin B₁ was continued, both intravenously and subcutaneously, in large doses. In this case it seemed to have been life saving.

CHART 1 The clinical course in Case 2

The next day the heart rate was 60 per minute, the circulation time 18 seconds, and the femoral arteriovenous oxygen difference 29 volumes per cent. The arterial pressure, venous pressure and colloid osmotic pressure of the blood were unchanged. On the second day after vitamin B₁ therapy was instituted the heart rate was as low as 52, the arterial pressure was 140 mm Hg systolic and 84 diastolic and the electrocardiogram (figure 8) showed increased voltage (10 mv). The circulation time was 25 seconds and the arteriovenous oxygen difference 31 volumes per cent. The slowing of the circulation shown by these measurements was all the more remarkable in view of the fact that the patient now had a fever due to cystitis and also, probably, to bronchopneumonia. The latter diagnosis could not be established because, while there were signs of dullness, bronchovesicular breathing and moist râles over the hilar regions of both lungs posteriorly, these signs might have been due simply to increased pulmonary congestion resulting from compensation of the right ventricle out of proportion to the left. We have observed these signs without fever in similar cases, and in this case the fever continued after the lungs had cleared and until the urinary infection was brought under control. The vital capacity decreased during this period, but later returned toward normal. On the third day of vitamin therapy the non-protein nitrogen, the bisulphite binding substances in the blood and the Q-T interval of the electrocardiogram were within normal limits. There was still no

change in the venous pressure or the colloid osmotic pressure of the blood. Clinically, in spite of the fever, the extremities were now cool, the sounds had disappeared over the brachial arteries and were barely audible over the femoral arteries. There was less edema, especially of the upper part of the body.

This patient's course was complicated by a prolonged febrile episode, due to the stubborn cystitis which required forcing of fluids. Nevertheless, he responded well to the vitamin therapy. On the sixth day of this treatment the edema had greatly decreased and the venous pressure was normal. The colloid osmotic pressure of the blood was still unchanged. He was then placed on a high vitamin diet, and after four days the parenteral vitamin B₁ was discontinued.

FIG 10 The cardiac shadow in Case 2 after treatment

Convalescence was steady and complete. The patient regained voluntary control of his bladder and the cystitis was relieved by mandelic acid. One month after admission a 7-foot roentgenogram showed that the heart had decreased to normal size (figure 10). Except for a flat T-wave in the first lead, the electrocardiogram was normal (figure 8). The vital capacity was 2,800 c.c. The patient had lost a total of 34 pounds. In the fifth week the knee jerks returned, and the strength was greatly improved. During the sixth week the patient was up and about the ward. He began to gain weight without edema. The protein content of the blood plasma was normal. Mentally, although greatly improved, he was still defective. His memory was poor and he confabulated. Consequently, at the end of the sixth week he was committed to a sanatorium for chronic care.

This patient was not seriously ill on admission, indeed, aside from the swelling of the scrotum there was no striking evidence of circulatory failure. He was placed on a low vitamin diet and all medication was withheld. On the third day there was no change clinically. Studies on that day showed the following: weight 185 pounds, arterial pressure 106 mm Hg systolic and 60 diastolic, heart rate 90 per minute, vital

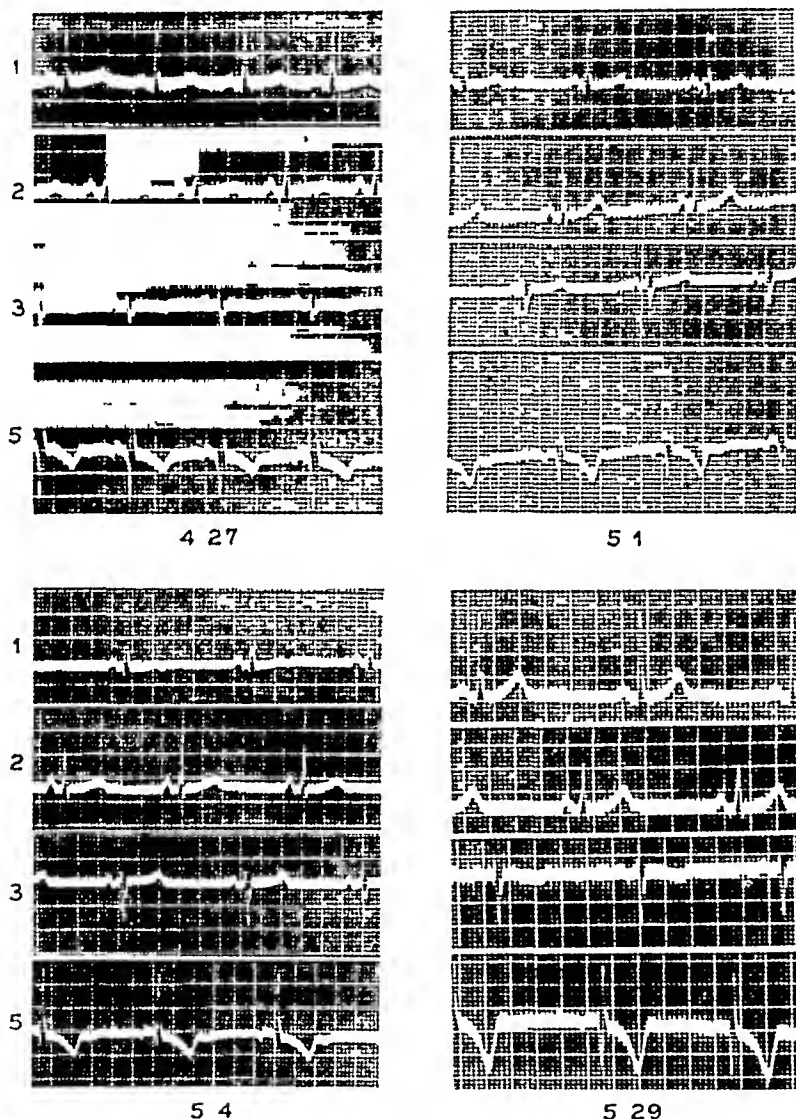

FIG 11 Electrocardiograms in Case 3. Note changes in T-waves.

capacity 2,600 c.c., venous pressure 10 cm. H₂O, circulation time 12 seconds, the femoral arteriovenous oxygen difference 20.8 volumes per cent. The total protein content of the blood plasma was 5.07 gm. per 100 c.c., the albumin 3.28 gm. and globulin 1.79 gm., with a calculated osmotic pressure of 210 mm. H₂O. The electrocardiogram showed no abnormality (figure 11). A 7-foot roentgenogram of the heart showed the heart enlarged as observed clinically.

After these observations vitamin B₁ was given intramuscularly in 5 mg doses twice daily. The clinical course and circulatory measurements are shown in chart 2. The striking changes one day after the vitamin were the slowing of the heart rate to 66 per minute and of the circulation time to 25 seconds, and the increase in the femoral arteriovenous oxygen difference to 4.09 volumes per cent. The venous pressure had risen slightly to 13.5 cm H₂O. There was also a striking change in the clinical appearance of the patient. His face, previously bright pink, was now definitely cyanotic, the hands and feet were quite cool, only the faintest sound could be heard over the carotid artery and no sound over the femoral or brachial arteries.

Four days after vitamin therapy was instituted the heart rate was 52 per minute, the blood pressure had risen to 152 mm Hg systolic and 90 diastolic, the vital capacity had increased to 3,100 cc and the patient had lost 12 pounds of edema fluid, in spite of the fact that there was no essential change in the venous pressure or colloid osmotic pressure of the blood. Marked clinical improvement coincided with these circulatory changes. In 10 days following the vitamin therapy the patient had lost 20 pounds of weight, and the vital capacity, the blood pressure, heart rate, venous pressure and femoral arteriovenous oxygen difference had returned to normal. An interesting change in the electrocardiogram at this time was the inversion of the T-wave in Lead I, which subsequently reverted to normal (figure 11).

At the beginning of the third week the parenteral injection of vitamin B₁ was stopped, and a high vitamin diet started. The knee jerks returned in the middle of the fourth week. At the end of the fourth week a second course of parenteral vitamin B₁ was given, exactly as before, with no effect on any aspect of the circulation.

The patient was discharged well at the end of the sixth week.

Case 4 Congestive failure of the circulation, the only manifestation of vitamin deficiency, when treated with digitalis and diuretics showed little improvement, on vitamin B₁ striking improvement. J. F., an unemployed waiter, aged 60 years, for four years had spent but 25 cents a day on food which was grossly inadequate in vitamins. He had taken an average of 10 glasses of ale and 2 glasses of whisky daily for one year. He complained of cough for six months, dyspnea on exertion for one month, orthopnea for two weeks, increasing dependent edema for 10 days and swelling of the abdomen for one week.

The family history showed that one brother died of alcoholism. The past history was non-contributory.

Physical examination showed an elderly, apparently well-nourished man, with severe orthopnea, and extreme dyspnea on the slightest exertion. His color was cyanotic, but at times only slightly so. There was marked dependent edema up to the sternum. The skin of the face and extremities was warm and dry. There was moderate engorgement of the veins of the neck. The heart was percussed 11 cm to the left and 5 cm to the right of the midsternal line. There was a rough blowing systolic murmur heard over the entire precordium, loudest at the apex. The heart rate was 120 per minute and the rhythm was regular except for occasional extrasystoles. The arterial pressure was 140 mm Hg systolic and 80 diastolic. Loud sounds were heard over the carotid and femoral arteries. Percussion of the chest revealed diminished resonance posteriorly at both lung bases, where moist rales were heard. The abdomen was tensely distended, with shifting dullness in the flanks and a palpable fluid wave. No organs were felt. The neurological examination was negative. Temperature 98° F. Respirations 30 per minute. Weight 184 pounds.

Laboratory studies. *Urine*, acid, specific gravity 1.015, albumin 0, sugar 0, bile 0, acetone 2 plus, diacetic acid 0, pyruvic acid 0, sediment, many leukocytes. *Blood*, hemoglobin 85 per cent, erythrocytes 3,700,000 per cu mm, leukocytes 12,400, neutrophils 85 per cent. The non-protein nitrogen was 28 mg per 100 cc, the fasting

blood sugar 94.1 mg per 100 cc and the carbon dioxide capacity 79.2 volumes per cent. The total protein content of the plasma was 4.8 gm per 100 cc, albumin 2.57 gm, globulin 2.23 gm, calculated osmotic pressure 178 mm H₂O. Icterus index 20. The Hinton test was negative. The Takata-Ara test was positive. Bisulphite binding substances in the blood (calculated as pyruvic acid) were 12.89 mg per 100 cc. *Lidema fluid* from the thighs showed a total protein content of 0.34 gm per 100 cc,

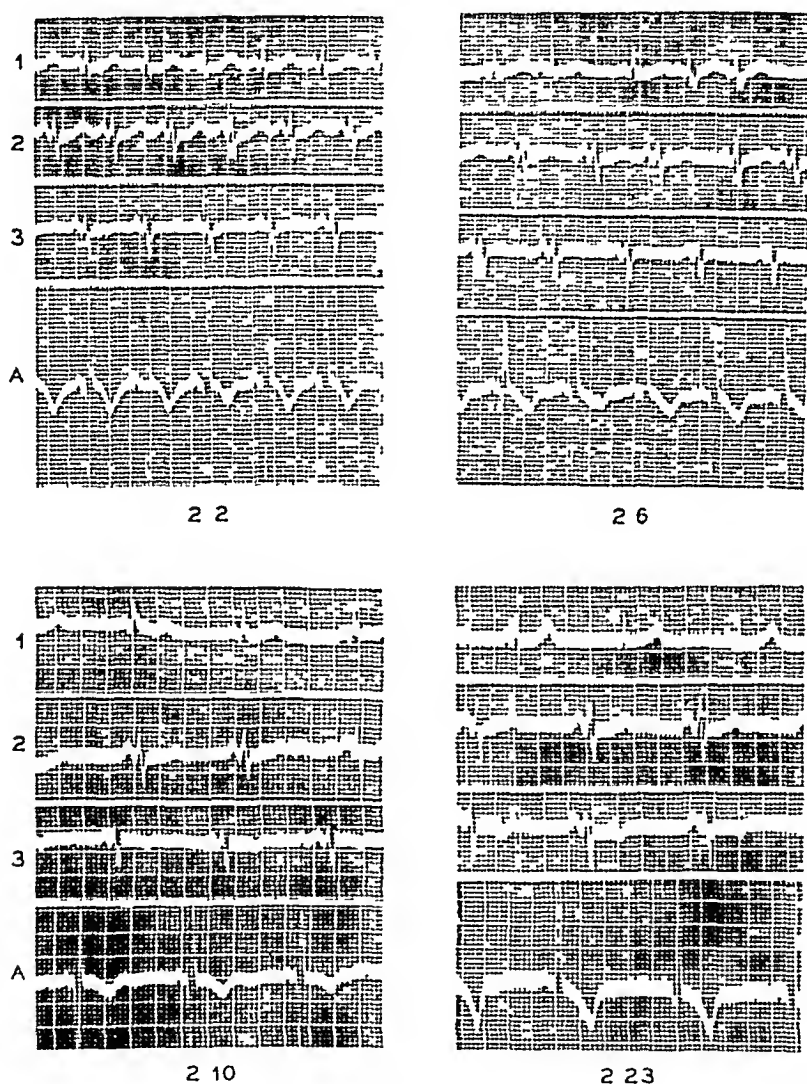

FIG 12 Electrocardiograms in Case 4. Note changes in rate and in T-waves.

albumin 0.095 gm, globulin 0.234 gm. The vital capacity was 1000 cc and the venous pressure 17 cm H₂O. The electrocardiogram showed tachycardia, low voltage (6 mv) and prolonged Q-T interval (K equals 0.52), suggesting myocardial disease (figure 12).

Because of the patient's precarious condition, his age, and the finding of a loud systolic murmur at the apex of the heart, it was deemed wise to treat him at once with

the standard cardiac drugs but to withhold vitamin therapy. Accordingly, he was put on a Karel diet (boiled milk), was digitalized rapidly and was given ammonium chloride, Aminophyllin and Salyrgan (two doses of 2 c c intravenously) as diuretics. Morphia was used as a sedative with marked subjective relief. There was a fall in pulse rate but no diuresis—the daily output ranged from 700 to 1,100 c c. This regime was maintained for four days, and on the fifth day the following observations were made: arterial pressure 145 mm Hg systolic and 82 diastolic, heart rate 80 per minute, venous pressure 15 cm H₂O, circulation time 13 seconds, femoral arteriovenous oxygen difference 3.66 volumes per cent. The vital capacity was 1,250 c c. The

FIG 13 The cardiac shadow in Case 4 before vitamin B₁ treatment.

total protein content of the blood plasma had risen to 5.38 gm per 100 c c, albumin 2.67 gm, globulin 2.71 gm, producing a calculated osmotic pressure of 200 mm H₂O. This was evidence of hemoconcentration, as the values two days later had fallen to and below their previous levels. A 7-foot roentgenogram showed the heart still enlarged to the left and right (figure 13).

On the fifth day *all medication* was omitted, and the deficient diet continued unchanged. Synthetic crystalline vitamin B₁ was given in 10 mg doses subcutaneously five times a day. The next day the urine output was 1,500 c c and rose progressively to reach a peak of 4,800 c c four days after the vitamin was started.

The clinical course and circulatory measurements are shown in chart 3. Of particular interest on the second day after vitamin therapy were the elevation of the blood pressure to 160 mm Hg systolic and 90 diastolic, the slowing of the heart rate to 60 per minute, the increase in the circulation time to 25 seconds and the increase in the arteriovenous oxygen difference to 48 volumes per cent. The venous pres-

CHART 3 The clinical course in Case 4

sure and colloid osmotic pressure of the blood were still essentially unchanged, but subsequently became normal, as did the blood pressure, the heart rate and other aspects of the circulation.

The clinical improvement coincident with these changes was dramatic. Except for a brief febrile episode with signs of bronchopneumonia on the sixth day after vitamin treatment, the course was one of steady improvement. The patient lost 51 pounds of weight in 12 days. He was then seen to be a thin-faced, frail individual, rather than the well-nourished man he had seemed on admission. The cyanosis, the orthopnea and the dyspnea on exertion disappeared, while the vital capacity rose to a normal value.

On the eleventh day a high vitamin diet was begun. In the fifth week, when all the circulatory measurements had been normal for one week, the same course of vitamin B₁ was repeated with no effect whatever. The patient was discharged well at the end of the fifth week. The 7-foot roentgenogram (figure 14) showed that the heart had returned to normal size.

Case 5 Congestive failure of the circulation, cardiac asthma, polyneuritis, mild psychosis, improvement on high vitamin diet and continuous high alcohol intake

O O, a corsetiere, aged 37 years, had consumed one pint of whisky daily for seven years. Her diet was meager, rarely contained vegetables or meat, and consisted principally of coffee, tea, and sandwiches of white bread.

FIG 14 The cardiac shadow in Case 4 after improvement

She complained of intermittent weakness and numbness in the feet for six years, increasing and progressing upward to involve the legs and finally the hands for three months. For two years she had had palpitation and dyspnea on exertion, and for one year swelling of the ankles. She also complained of orthopnea for three weeks, and nocturnal attacks of paroxysmal dyspnea for two weeks.

The family history revealed that the paternal relatives were alcoholics, otherwise it was non-contributory. The past history was non-contributory.

Physical examination showed a well-nourished, mildly psychotic, apprehensive orthopneic woman with marked edema of the legs. The skin was thick, warm and moist. The veins of the neck were distended. The heart was percussed 11 cm to the left and 5 cm to the right of the midsternal line. There was a gallop and a short blowing systolic murmur at the apex. The heart rate was 120 per minute and the rhythm was regular. The arterial pressure was 110 mm Hg systolic and 70 diastolic. The carotid and peripheral arteries showed increased pulsations. The lungs were resonant and clear. In the abdomen the liver edge was felt just below the right

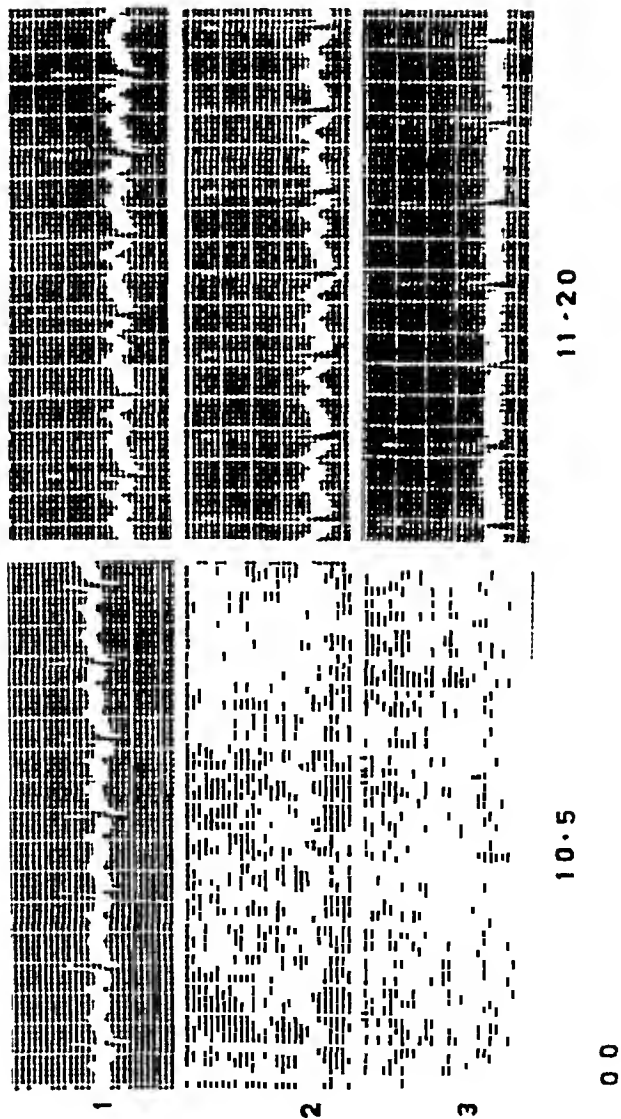

FIG 15 Electrocardiogram in Case 5. Note the return of the S-T complexes to normal following the continued administration of oral vitamin B concentrate and alcohol

costal margin There was bilateral toe drop, absent knee and ankle jerks, and absent vibration sense below the knees Temperature 99° F Respirations 25 per minute Weight 167 pounds

Laboratory studies *Urine*, acid, specific gravity 1.019, albumin 0, sugar 0, sediment, many leukocytes *Blood*, hemoglobin 82 per cent, erythrocytes 4,230,000 per cu mm, leukocytes 9,300, neutrophils 76 per cent The non-protein nitrogen was 60 mg per 100 cc of blood The total protein content of the plasma was 6.5 gm per 100 cc, albumin 3.25 gm, globulin 3.25 gm, with calculated osmotic pressure 264 mm H₂O The Kahn test was negative Roentgenogram confirmed the enlargement of the heart and showed congestion of the lung fields Electrocardiogram (figure 15) showed tachycardia, and abnormal T-waves suggesting myocardial disease

For five days the patient was kept on a house diet with no essential change in her condition She was then placed on a high vitamin diet, supplemented by oral yeast extracts and intramuscular liver extract In addition she was given one pint of whisky a day On this regime she improved rapidly The nocturnal dyspnea, the edema and palpitation disappeared Within two weeks the heart rate had decreased to 90 and the gallop had disappeared After six weeks the electrocardiogram was normal (figure 15) There was slower but steady improvement in the neurological and mental symptoms When discharged from the hospital, four months after entrance, she was able to walk satisfactorily and the psychosis had cleared, but some abnormal neurological signs still persisted in the legs She had continued to receive one pint of whisky daily until discharge

Case 6 *Acute cardiac dilatation and congestive failure associated with polyneuritis, improvement after rest, digitalis, good diet and oral vitamin "B" extract* W F, a laborer, aged 32 years, had consumed ½ pint of pure alcohol daily for five years He had eaten little food because of an extremely poor appetite He complained of increasing dyspnea on exertion for two years, increasing swelling of the legs for one year, and difficulty in walking associated with numbness of the feet and hands for six months The family history and the past history were non-contributory

Physical examination revealed a small but well-nourished man, comfortable, flat in bed with marked edema of the lower legs The skin was dry, warm and of good color The veins of the neck were distended and showed marked pulsations The heart was percussed 11 cm to the left and 6 cm to the right of the midsternal line The precordium was heaving rapidly A marked gallop was heard near the apex, where there were also loud, rough systolic and diastolic murmurs Over the aortic area blowing systolic and diastolic murmurs were heard The heart rate was 100 per minute and the rhythm was regular The arterial pressure was 130 mm Hg systolic and 60 diastolic There were marked pulsations of all peripheral arteries, over which loud "pistol" sounds were audible The lung bases were dull posteriorly In the abdomen the liver was palpated 4 cm below the right costal margin The knee and ankle jerks were not obtainable Temperature 100° F Respirations 20 per minute Weight 113 pounds

Laboratory studies *Urine*, first specimen acid, specific gravity 1.036, albumin 0, sugar 3 plus, bile positive, acetone 0, diacetic acid 0, sediment, negative Later specimens negative *Blood*, hemoglobin 78 per cent, erythrocytes 4,220,000 per cu mm, leukocytes 9,800, neutrophils 65 per cent The non-protein nitrogen was 22 mg per 100 cc, the fasting blood sugar on the third day 93 mg per 100 cc The total protein content of the blood plasma was 6.3 gm per 100 cc, albumin 3.4 gm, globulin 2.9 gm, with calculated osmotic pressure 260 mm H₂O The Kahn test was negative The Takata-Ara test was negative

A 7-foot roentgenogram of the heart on the second day showed enlargement (Figure 16) The electrocardiogram showed a flat T-wave in Lead I and prolonged Q-T interval (K equals 0.46), interpreted as myocardial disease

Because of the diastolic murmurs heard on admission it was thought that the patient had organic valvular heart disease. He was digitalized rapidly and given a high vitamin diet supplemented by oral extracts of vitamin B. On the second day no diastolic murmur could be heard. The improvement was rapid. On the seventh day he was allowed out of bed. The digitalis was omitted. A 7-foot roentgenogram at the beginning of the fifth week (figure 17) showed a small heart. He was discharged well in the sixth week.

FIG 16 The cardiac shadow in Case 6 on the first day after admission

Case 7 Repeated admissions for attacks of carotid sinus syncope and circulatory failure associated with polycystitis, relief after diet and extracts rich in vitamin "B" E S, an unemployed odd-job man, aged 47 years, had drunk one pint to one quart of liquor daily for years. He had eaten irregularly and his diet was of poor quality. He was admitted to the hospital on three occasions with essentially the same complaints. These were dizziness and attacks of syncope, soreness of the mouth and tongue, pain, weakness and numbness in the legs, nocturnal cough, dyspnea on exertion and nocturnal attacks of paroxysmal dyspnea.

Physical examination revealed a poorly nourished man with no orthopnea or edema. The skin was pale. The mucosa of the mouth and tongue was red, with patchy ulcerated areas covered by whitish exudate. The heart was percussed 7 cm to the left and 3 cm to the right of the midsternal line. There was a blowing systolic murmur at the apex. The heart rate was 110 to 120 per minute, and the rhythm was regular. The arterial pressure was 115/70 to 120/90 mm Hg. The abdomen was

FIG 17 The cardiac shadow in Case 6 following improvement

negative. The ankle jerks were not obtainable and the vibration sense was absent below the knees. Temperature 99° to 100° F. Respirations 20 to 25 per minute. Weight 135 to 145 pounds.

Laboratory studies. *Urine*, acid, specific gravity 1.020, albumin, bile, sugar and sediment negative. *Blood*, hemoglobin 55 per cent, erythrocytes 4,000,000 per cu mm, leukocytes 5,700, neutrophils 71 per cent. The non-protein nitrogen was 30 mg per 100 cc. The Kahn test was negative. *Lumbar puncture* revealed normal pressure and normal spinal fluid. *Gastric analysis* showed no free acid after his-

tamine. The 7-foot roentgenogram showed no abnormality of heart or lungs. The electrocardiogram showed flattening or inversion of the T-waves in Leads I and II, interpreted as myocardial disease.

On each admission under treatment with a good rest, intramuscular liver and vitamin "B" extracts, there was complete relief of the cardiovascular symptoms within two weeks. It is of interest that with improvement the blood pressure rose from 140/104 to 200/120 mm Hg. The improvement in the neurological symptoms was equally striking, but slower.

On the second admission it was found that even mild stimulation of the carotid sinus caused complete asystole of the heart and syncope. The patient stated that the induced attack was the same as the spontaneous spells of which he complained. Six days after vitamin therapy the dizziness had improved, and carotid sinus pressure now induced no asystole but an idioventricular rhythm with a rate of 30 per minute. Slight dizziness but no syncope accompanied the slowing. Four days later, and thereafter, stimulation of the carotid sinus induced only transient physiological slowing of the sinus rhythm and no dizziness. He was discharged improved in the third week.

DISCUSSION

The association of cardiovascular dysfunction with nutritional deficiency suggests a possible causative interrelation between the two conditions. Furthermore, the characteristics of the cardiovascular disturbances and the frequent coexistence of nervous disorders indicate a similarity between the condition observed and oriental beriberi. It was the primary purpose of this investigation to ascertain whether the disease studied is only similar to or is actually identical with the cardiovascular disturbances occurring in beriberi.

Beriberi is considered to be primarily an avitaminosis, and the polyneuritic form of the disease has been reproduced experimentally in animals fed a diet lacking in vitamin B₁. In spite of the fact that a descriptive knowledge of this disease dates back to ancient Chinese and Japanese records, the etiology and pathogenesis are but partially clarified. The cardiac form of the disease has heretofore been studied only in the Orient. In recent years particularly, extensive investigations on "beriberi heart" have been carried out in Java by Wenckebach and Aalsmeer^{10, 11}.

The Occurrence of Beriberi in the United States As recently as 1932 Wenckebach¹³ stated that "beriberi is, or is supposed to be an avitaminosis, which is met in such tropical countries only where rice is the prevailing food." Nevertheless, scattered reports are available on the occurrence of beriberi in other parts of the world, including the United States. Scott and Herrmann¹⁴ have reported cardiac manifestations among rice workers in Louisiana. Kep'ler¹⁵ has observed one and Riesman and Davidson¹⁶ two suggestive cases with cardiac manifestations. There are also a few reports on polyneuritis due to food deficiencies, in which the authors considered the clinical syndrome identical with beriberi. Wohl¹⁷ described such a poly-

* Since this paper was sent in for publication, B. Sure and W. A. Jones have reported (personal communication) a study on the role of vitamin B₁ in cardiovascular diseases in 30 patients at the U. S. Veteran's Hospital, Fayetteville, Arkansas.

neuritic form of beriberi in a young diabetic patient who lived on an unbalanced diet

Minot, Strauss and Cobb concluded that in alcoholic polyneuritis the etiological factor is vitamin B deficiency, rather than excessive use of alcohol. Jolliffe, Colbert and Joffe¹⁸ have demonstrated that, according to Cowgill's formula, the vitamin B (B_1) intake of alcoholic patients with polyneuritis is decreased to well within the limit required for the induction of polyneuritis in animals. Among the patients with polyneuritis and pellagra whose records are on file in the Boston City Hospital, consumption of a large amount of alcohol, usually over a prolonged period, frequently occurred. In comparing the clinical characteristics of "alcoholic pellagra" and "nonalcoholic pellagra," Spies¹⁹ observed no difference between the two types. Our clinical experience, similarly, fails to reveal any difference between alcoholic and nonalcoholic deficiency polyneuritis and pellagra. These considerations strongly suggest that the polyneuritis and pellagra observed in both alcoholic and nonalcoholic patients with food deficiency are of similar, if not identical, etiology, and that both of these conditions bear a causative relationship to the avitaminosis.

"Beriberi Heart" as Heretofore Described There are mainly two explanations of the pathogenesis of "beriberi heart." The older theory, advocated by early Japanese workers, is that the cardiac disease is caused by a disturbance of the function and a "degeneration" of the *vagus nerves*.²⁰ The frequent observation of rapid heart and the demonstration of demyelination of the vagus nerves were offered as evidence for this theory. The histological evidence of structural changes in peripheral nerves is, however, inadequate. Some of the cases studied by us showed histological changes within the vagus centers.

Lately the vagus theory has given way to the myogenic theory. Wenckebach¹³ considers the essential change in the heart to be degeneration of the muscle which "robs the heart of its means of resistance to stretching, and deadens its power of contractility." In addition there is widening of the peripheral arterioles which results in a rapid and increased volume flow to the right side of the heart. The right ventricle, unable to take care of this inflow, becomes dilated and the syndrome of right ventricular failure develops. According to these investigators, dilatation of the right side of the heart, in the presence of clear lungs as evidenced by physical and roentgen-ray examinations, and the exaggeration of peripheral vascular signs after the administration of epinephrine and their diminution after pitressin constitute the main characteristics of "beriberi heart." The reports of Keefer²¹ and others indicate, however, that the most common disturbances in "beriberi heart" in China are tachycardia, palpitation and excessive fatigue, and that pure right-sided dilatation is not an essential manifestation.

Aalsmeer and Wenckebach^{10,11} observed no essential electrocardiographic changes in patients with "beriberi heart" in Java. At times pa-

tients with severe circulatory disturbances showed a *shortened* P-Q conduction time, which became normal as the condition improved. Keefer²¹ has described low voltage and negative T₁ waves in some of the cases observed in China.

Cardiovascular Changes in Experimental Vitamin B₁ Deficiency So far as is known at present, deficiency of vitamin B₁ is the only vitamin deficiency which is followed by cardiac disturbances.* Carter and Drury²² showed that pigeons fed a diet of polished rice developed bradycardia and heart-block. These changes were of vagal origin, as section of the nerve or atropine abolished them. In an electrocardiographic study of vitamin B deficiency in the rat, Drury, Harris and Maudsley²³ observed a bradycardia of 300 or 350 per minute, as compared with a normal rate of 500 to 525. In this animal the bradycardia was of sinus origin, and not due to vagal influence. So characteristic is this response that it is used to test diets for vitamin B₁ deficiency. These observations show that the cardiac disturbance can vary in different species.

The experimental studies did not reveal changes in the complexes of the electrocardiograms. As far as one can ascertain, however, the electrocardiograms obtained in rats were not standardized. Because the patients with nutritional deficiencies showed changes in the electrocardiographic complexes, a study was undertaken to ascertain whether similar changes develop in the standardized electrocardiograms of rats deficient in vitamin B₁.²⁴ The results of this study indicate that rats on B₁ deficient diets develop not only bradycardia but also changes in the electrocardiographic complexes, such as increased height of the S-T segment and flattening or inversion of T-waves. Subcutaneous administration of from 5 to 28γ of crystalline vitamin B₁ (Merek) abolished within 6 to 12 hours both the bradycardia and the changes in the complexes. These electrocardiographic changes are in harmony with those described in human beings.

Central Nervous System Changes in Experimental Vitamin B₁ Deficiency That deficiency of vitamin B₁ is associated with failure in certain oxydase systems has been known since 1918.²⁵ Peters and his associates^{27, 28} have shown that in vitamin B₁ deficiency the oxygen utilization of the brain is reduced. After adding vitamin B₁ to deficient brain tissue of the pigeon and the rat *in vitro*, the oxygen consumption increased and the pyruvate formed by the avitaminous brain decreased. The degree of biochemical change was not the same in all parts of the brain. These workers concluded that the symptoms of avitaminosis observed in the rat and pigeon are of central origin.^{28, 29} Church³⁰ has shown that the vestibular function is significantly altered in rats with vitamin B (B₁) deficiency. The fact that these striking changes in function, referable to vestibular nuclei, disappeared within as short a period as a few hours indicates that a central metabolic disturbance, rather than organic degenerative lesions, was responsible.

* It is probable that the myocardial disturbances reported in rickets and scurvy are caused by the simultaneous presence of vitamin B₁ deficiency.

Evidence of the Nutritional Origin of the Cardiovascular Dysfunctions

The following evidence supports the nutritional and particularly the vitamin B₁ origin of the disturbances of the cardiovascular system described (a) In the majority of the cases studied there was unbalanced food intake with adequate supply of calories and with maintenance of normal body weight. A calculation of the vitamin B₁ content of the food in relation to the caloric intake was below the normal requirement of man and within the limit necessary for the development of B₁ deficiency, as indicated by Cowgill. The diet of these patients was therefore similar to that described recently by Jolliffe, Colbert and Joffe¹⁸ in alcoholic addicts with polyneuritis. In a smaller group of patients the vitamin "B" intake seemed to be adequate but the presence of changes in the gastrointestinal canal apparently prevented its utilization. (b) None of the recognized etiological factors of cardiovascular disease were present in the "pure" cases studied. The clinical, physiological and morphological findings did not correspond to those observed in the recognized diseases of the cardiovascular system. (c) The cardiovascular disturbances were frequently associated with disturbances in other systems, which were of the type attributed to vitamin "B" deficiencies. (d) Just as in oriental beriberi, the patients with a severe degree of circulatory failure were not apt to have severe polyneuritis, and vice versa. (e) The dilatation of the peripheral arterioles, the relatively or absolutely increased velocity of blood flow with increased venous pressure, the dilated heart, the severe generalized edema, the vascular sounds associated with bounding pulsation, as well as the occurrence of vasomotor collapse, indicate a similarity between "beriberi heart" as described in the Orient and the condition observed in Boston. (f) The electrocardiographic changes observed in human beings are similar to those found in rats deficient in vitamin B₁. (g) All the characteristics of the disturbances observed in man usually disappear after rest and the administration of vitamin B₁ or a diet rich in vitamin B₁.

Differences Between the Circulatory Disturbances Observed and Those Reported in "Beriberi Heart" There were a number of differences between the characteristics of the cardiovascular dysfunctions observed in Boston and those described as "beriberi heart" in the Orient. In contrast to the patients observed by Aalsmeer and Wenckebach in Java, the group here reported usually did not exhibit a pure right-sided failure of the circulation. Patients with cardiac dilatation, peripheral arterial sounds, rapid peripheral flow and engorged veins were observed, but other patients with an identical type of deficiency showed pulmonary engorgement with dyspnea, cardiac asthma, orthopnea and other manifestations of left-sided failure. In a few patients vasomotor collapse developed in its pure form. Electrocardiographic changes with tachycardia were present in some patients without any other abnormality. There were again instances in which at different stages of the disease various combinations of these changes occurred.

Hence the cardiovascular disturbances caused by nutritional defects do not form a rigid clinical syndrome. We wish also to emphasize that the term "beriberi heart" is inappropriate because of the widespread nature of the circulatory disturbances in this disease. Wenckebach himself indicates that the primary change is a peripheral dilatation, and that the heart is only secondarily involved. Whether the clinical differences between oriental "beriberi heart," particularly as described in Java, and the cardiovascular disturbances in the group here reported are due to actual differences in some aspects of their pathogenesis, or to the fact that the type reported by Aalsmeer and Wenckebach represents but one form of the disease existing in Java, it is impossible to state. In the production of vitamin deficiencies in animals, factors other than vitamins play important rôles. In man, in the majority of instances there are multiple avitaminoses, and the number of variables is even greater. The composition of the food, the functions of internal secretory glands, the intensity of muscular work, and the time element in the development of the deficiency may well have an important bearing on the variability of the clinical picture. The relative significance of the interrelation between these factors is not known at present.

In the Orient it is recognized that persons who perform strenuous muscular exercise, and who do not exhibit polyneuritis, form the group which is liable to develop cardiac dilatation and other circulatory symptoms. In this part of the United States vitamin "B" deficiencies occur mainly in alcoholics, and less frequently in pregnant women, in persons without work and hence in poverty, in "food cranks," in patients with diabetes or with certain types of gastrointestinal diseases. Such persons seldom, if ever, perform prolonged hard work. This may well be important in determining the somewhat different aspect of the disease as observed in the Orient and in Boston. That deficiency of vitamins is not the sole determining factor in these clinical syndromes is clearly indicated by the fact that not all patients with the same degree of vitamin deficiency develop symptoms, and also by the fact that the same degree of deficiency can produce different symptoms in different subjects. Furthermore pure vitamin deficiency, particularly a deficiency of B_1 (polyneuritis) or of B_2 (pellagra), is rare. In the majority of cases on record in the Boston City Hospital pellagra and polyneuritis occurred in combination. On the other hand, polyneuritis and pellagra were rarely associated with an *advanced* degree of scurvy.

Changes in the Electrocardiogram and Their Relation to Vitamin B_1
The electrocardiographic changes observed by us were essentially the same as those reported recently by Feil³¹ in a group of patients with pellagra. It is significant, however, that in our group with nutritional deficiencies, electrocardiographic changes of identical nature were observed not only in pellagra without polyneuritis, but also in polyneuritis without pellagra, and in cases with food deficiency without either pellagra or polyneuritis. Conversely, electrocardiographic changes were not necessarily present in all pa-

tients with any of these deficiencies. In view of the fact that similar electrocardiographic changes were induced in rats with vitamin B₁ deficiency, and in patients without pellagra, we attribute the electrocardiographic changes to deficiency of vitamin B₁ rather than of other fractions of the "B" group. It is of interest and in harmony with observations in man that in the same rat the electrocardiographic changes may be different or may even be absent in repeated instances of vitamin B₁ deficiency. This is further evidence that in B₁ avitaminosis the disturbances even within one organ, such as the brain or heart, may vary, depending upon their particular focal localization.

Porter and Higginbotham³² have claimed recently that not a single case of pellagra observed by them exhibited congestive failure of the circulation or increase in the size of the heart. They conclude that in pellagra no characteristic change occurs in the cardiovascular system and that pellagra and beriberi have no comparable effect on the heart. This difference, according to Porter's belief, is absolute and means that vitamin B₁ is not concerned with the pathogenesis of pellagra. He ventures that "many of the diseases produced by avitaminosis affect, in a selective manner, certain tissues of the body, and one can anticipate precisely the kind of deficiency by noting the structures involved and the character of the tissue reactions." Porter interprets the electrocardiographic changes observed in pellagra as having no relation to beriberi or to deficiency of vitamin B₁. In support of this he quotes Wenckebach's "unequivocal statement" that the electrocardiogram in beriberi is normal, with the exception that the conduction time is shortened. Such a contention is not in agreement with our findings. Our interpretation of our own observations, as well as of those of Feil and of Porter, is that the cardiovascular disturbances in vitamin "B" deficiencies are more varied than is claimed by Wenckebach in beriberi or by Porter in pellagra, and that deficiency of B₁ is the primary cause for all these disturbances. Cardiovascular disturbances are apt to be present in pellagra as well as in beriberi, because in man vitamin B₁ deficiency usually occurs in combination with B₂ deficiency.

The Rôle of Alcohol As the majority of the patients observed consumed large amounts of alcohol, the rôle of alcohol in the development of cardiovascular manifestations requires special consideration. There is valid evidence indicating that alcohol per se cannot be primarily responsible for the manifestations observed. In the first place, chronic alcoholism is exceedingly common, while the condition described is relatively rare, hence a simple causative relationship does not exist. Furthermore, pharmacological studies do not reveal that pure alcohol per se causes persistent cardiovascular damage or polyneuritis, such as occurs in beriberi. In a group of patients with polyneuritis associated with alcoholism Strauss³³ has shown that the polyneuritis improved following the administration of vitamin B extracts and of amounts of alcohol similar to those consumed by

the patient during the development of the polyneuritis. Four patients of the group studied by Strauss, who are included in our series, showed cardiovascular changes which improved under the experimental therapeutic regime *containing alcohol*. Further evidence against the primary rôle of alcohol is that in spite of the fact that many of the patients with severe degrees of circulatory failure and polyneuritis discontinued the consumption of alcohol many weeks before the observations were made, the condition grew rapidly worse or actually developed during the withdrawal period. This was particularly true in patients with persistent anorexia, nausea, vomiting and diarrhea. If alcohol, a rapidly oxidizable substance, were a primary "toxic agent" this would not be likely to occur.

In the light of present knowledge, nevertheless, we attribute to alcohol the following *secondary* predisposing roles in the precipitation of the cardiovascular dysfunctions and of vitamin deficiencies in general. (a) Alcohol is a food substance *par excellence* in this part of the world, and it supplies the body with the necessary calories but with a minimum of vitamin "B," an ideal combination of factors for the development of "beriberi." It should be recalled that the caloric value of a pint of pure alcohol is about 3,500 calories. In addition, the consumption of large amounts of alcohol tends to produce gastritis, achlorhydria, persistent nausea and diarrhea, which in turn further interfere with the utilization of vitamin "B." Such patients frequently claim that even with special effort they are unable to take appreciable amounts of food (Case 6). (b) There is possibly another specific, though secondary, role of alcohol in beriberi. It is known that the composition of the diet in terms of carbohydrate, protein and fat has a significant relation to the development of beriberi. Abderhalden and Wertheimer³⁴ have demonstrated that if vitamin B deficient pigeons are fed fatty acids instead of carbohydrates, muscular cramps characteristic of the deficiency do not develop. Several observers have claimed that a high carbohydrate diet in animals and a pure rice diet in man predispose to clinical vitamin B₁ deficiencies. Alcohol, as a carbohydrate, in large amounts may act in the same way. The tendency of diabetic patients to develop polyneuritis and cardiovascular dysfunction is probably due to the combined effects of an abnormal metabolism and a high carbohydrate, low vitamin diet.

The importance of alcohol in vitamin B deficiency has been demonstrated experimentally by the recent study of Wechsler, Jervis and Potts³⁵. These investigators showed that the severity of the nervous symptoms of monkeys maintained on alcohol and a vitamin B₁ deficient diet cannot be referred to the avitaminosis alone. The clinical course of the B₁ avitaminosis was aggravated by continuous alcohol intoxication. They concluded that the combination of alcohol and B₁ avitaminosis is particularly noxious to the nervous system.

Pathogenesis of the Cardiovascular Dysfunctions The results of

animal experimentation favor the concept that most of the manifestations of B_1 deficiency depend on disturbances of nervous functions, particularly in the central nervous system^{29, 30} The most frequent manifestations of beriberi in the Orient, as well as in the United States, consist in polyneuritis, psychosis, vertigo, cough and dysphagia, which are also nervous in origin The question then arises as to whether the cardiovascular dysfunctions depend primarily on nervous, on local myocardial or on vascular changes The instances of tachycardia followed by bradycardia, as well as the instances of irritable carotid sinus reflex, indicate that some of the manifestations depend on disturbance of the vagus system The tendency to vasomotor collapse and the dilatation of peripheral arterioles, which constrict after the administration of crystalline B_1 , may be, at least theoretically, central in origin Some of the changes, especially those in the electrocardiogram, may be due to local myocardial disturbances Other manifestations, such as cardiac dilatation, are explicable as secondary to the rapid peripheral blood flow The exact pathogenesis of the cardiovascular dysfunctions, however, is not known at present

The response of patients with beriberi to therapeutic measures also requires further study Patients observed by us as well as those observed in China and in Labrador show considerable variation in rate of improvement Moreover, in the same patient the dilatation of the arterioles and the prolongation of the electrical systole disappear promptly, the edema, decreased vital capacity and elevated venous pressures disappear more slowly, while the dilated heart and abnormal electrocardiographic complexes return to normal only after several weeks of treatment These variations in rate of improvement indicate that in man primary vitamin B_1 deficiency, when chronic, is followed by secondary changes of slow reversibility The gross and microscopic studies of the heart corroborate this contention Cardiac dilatation and, occasionally, hypertrophy, "hydropic" degeneration of the myocardial fibers and increase in intercellular substance (collagen) are evidences of myocardial damage That these do not represent simply "myocardial edema" is shown by the unaltered water content of the myocardium Such a transition from chemical disturbances to physiological and ultimately to structural changes is not peculiar to the cardiovascular system in vitamin B_1 deficiency Changes of a similar nature occur in the central and peripheral nervous systems and probably also in other organs They are comparable to the disturbed functions and lesions of the nervous system, intestinal tract and skin in pellagra, and of the spinal cord in pernicious anemia

Clinical and Therapeutic Implications in the Cardiovascular Dysfunctions Associated with Vitamin Deficiencies The therapeutic indications for patients with definite vitamin deficiency are obvious They should receive a well-balanced diet of adequate caloric value, rich in vitamin "B" In resistant or severe cases the parenteral administration of pure vitamin

B₁ or its extracts is indicated because such patients often suffer from anorexia with constipation or with diarrhea, and consequently have not only a low intake but also an impaired utilization of food.

It is well to bear in mind that patients with chronic organic heart disease may have, in addition, cardiovascular disturbances related to avitaminosis. The nutrition of patients with chronic heart disease, especially with congestive failure, is frequently poor. It is particularly important to give such patients a balanced diet rich in vitamins.

The doses of crystalline B₁ administered were larger than those indicated by experimental evidence. Such large doses were given mainly because there is available no clinical test which could be used as a guide for the adequacy of the dosage. It is of interest that no toxic reactions were observed, either in deficient or in non-deficient patients, following the intravenous administration of a dose as large as 50 mg. In some patients with dilated peripheral arterioles a temporary elevation of the arterial pressure followed the administration of crystalline vitamin B₁. Beneficial effects from crystalline vitamin B₁ were not observed in other diseases, including heart failure and edema, in which there was no vitamin B₁ deficiency.

Cowgill⁹ has demonstrated that the tendency to develop polyneuritis varies directly with the metabolic rate of the body, and inversely with the vitamin B (B₁) intake, hence the conditions favorable for the development of "B" avitaminosis are quite different from those associated with general starvation and inanition. Because the available evidence also strongly suggests that the cardiovascular dysfunction is closely related to, if not caused by, vitamin B (B₁) deficiencies, any condition associated with prolonged high metabolism and low intake of vitamin B₁ will be particularly liable to result in clinical avitaminosis with cardiovascular disturbances. Strenuous work, hyperthyroidism and infectious diseases with fever are such bodily states. Hyperthyroidism is usually associated with an increased appetite and with the consumption of a well-balanced diet. In rare instances, however, it may be accompanied by anorexia and persistent diarrhea, and in such cases cardiac dilatation, polyneuritis and psychosis may be present. It is interesting that Chvostek³⁶ quotes the literature up to 1917 on the association of polyneuritis with hyperthyroidism. Means³⁷ also describes suggestive cases of hyperthyroidism and vitamin "B" deficiency.

It is known, and our experience bears this out, that to patients with deficiency polyneuritis and pellagra, both of the alcoholic and of the non-alcoholic type, infections in general, and pneumonia in particular, represent grave danger. The circulation in patients with infections is comparable to that in persons performing heavy and continuous exercise. Fever per se increases the work of the heart and the rate of the circulation. It also is associated with a rise in the metabolic rate and usually with anorexia, which further accentuate a preexisting avitaminosis, as well as the associated cardiovascular dysfunctions. In a similar way the ordeal of general anes-

thesia and surgical operation may increase to the breaking point the strain on the heart and circulation of "B" avitaminotic patients

The relation of vitamin B (B_1) to infection and high metabolism explains the origin of the infectious theory of beriberi, and the occurrence of "epidemics" of beriberi. Prolonged infections, such as malaria in the tropics, will tend to aggravate the existing deficiencies, and will bring to the surface underlying or "subclinical" deficiencies. In these cases therapeutic procedures which terminate the infection or reduce the fever, together with the administration of a well-balanced diet and vitamin B concentrate or parenteral preparations, may well be life saving.

The data here presented, we appreciate, do not offer final proof of a direct relationship between cardiovascular manifestations and deficiency of vitamin B (B_1) or of any other vitamin. This problem is still open, even as far as classical "beriberi heart" of the Orient is concerned. In this study an attempt was made only to present clinical evidence on the thesis that (1) cardiovascular disturbances do occur in association with vitamin "B" types of deficiency, often with adequate or more than adequate caloric intake, (2) while the clinical picture of this condition is variable, nevertheless it is similar in several respects to that of "beriberi heart" observed in the Orient.

The observations here described also serve to demonstrate that not only pellagra, but also beriberi, occurs in Boston. This completes the picture, showing that all known types of avitaminosis attributed to the vitamin "B" group, as well as to other types of vitamins, are present in the northeastern and probably other parts of the United States.

SUMMARY AND CONCLUSIONS

1 Dysfunction of the cardiovascular system resulting from unbalanced food intake is a disease of regular occurrence in the United States. This report is based on a study of 120 such cases, 35 of which were investigated within two years.

2 The cardiovascular manifestations depend on changes in the nervous system, in the vascular system and in the myocardium.

3 Tachycardia followed by bradycardia, gallop rhythm, vagal reflex irritability, dilatation of the heart, dyspnea, orthopnea and pulmonary congestion, associated with bounding arterial pulsation, arterial "pistol" sounds, engorged veins, warm skin and edema are the usual clinical features of severe cases.

4 The hemodynamics are characterized by low vital capacity of the lungs, high venous pressure and normal arterial pressure, and by a relatively or absolutely increased velocity of blood flow and decreased peripheral utilization of arterial oxygen. The osmotic pressure of the blood is usually moderately low and frequently remains essentially unchanged while the edema disappears.

5 The electrocardiograms were normal in but 7 per cent of 67 cases. The main abnormalities consisted in changes in the T-waves and prolongation of the electrical systole (Q-T). The electrocardiographic changes in patients with pellagra or beriberi probably are due to the B₁ component of the vitamin deficiency.

6 The myocardium often showed "hydropic" degeneration of the muscle and conductive fibers and increase in the intercellular substances, but unaltered water content.

7 The cardiovascular disturbances caused by nutritional deficiencies do not form a rigid clinical syndrome. Right ventricular failure, left ventricular failure, arteriolar dilatation and increased blood flow, peripheral circulatory collapse and shock, singly or in combination, have been observed.

8 The onset of the disease may be sudden or gradual. Patients with the severe form of the disease show a tendency to fever, to bronchopneumonia and to acute fatal circulatory collapse. Under therapeutic measures such as rest, cardiac drugs, diets rich in vitamin B₁ or crystalline vitamin B₁, all the cardiovascular disturbances usually revert to normal.

9 The clinical symptoms and signs, the blood chemistry, the myocardial changes, the hemodynamics and therapeutic responses correspond to those described in "beriberi heart" in the Orient. The disease as observed in Boston, however, is characterized by more varied and more generalized involvement of the cardiovascular system.

10 Evidence is presented indicating that vitamin B₁ deficiency plays a primary rôle in the precipitation of the disease. Alcohol also is a significant factor, not only because it supplies calories without vitamin B₁, but also because its metabolic effect is similar to that of a pure carbohydrate.

11 The rate of response to vitamin B₁ in "alcoholic" and "nonalcoholic" beriberi varies. The arteriolar system shows a more rapid change than the heart. The cardiovascular disorder usually disappears before the polyneuritis. The factors influencing therapeutic responses are discussed.

12 In normal subjects, as well as in patients with diseases other than vitamin B₁ deficiency, even large doses of crystalline vitamin B₁ produce no appreciable effects.

13 The condition here described bears pertinently on the clinical behavior and the mortality rates of alcoholic and nonalcoholic patients with vitamin "B" deficiencies (beriberi and pellagra). It may explain the poor reaction of these patients to increases in metabolic rate, such as occur in febrile infections, in hyperthyroidism, or under surgical operations. The therapeutic indications under these conditions are discussed.

This study was conducted with the assistance of Dr Florence W Haynes and Miss Sophia M Simmons.

CHRONIC BILATERAL PYELONEPHRITIS ITS ORIGIN AND ITS ASSOCIATION WITH HYPERTENSION

By WARFIELD T. LONGCOPE, F A C P, *Baltimore, Maryland*

THE continuous study of 22 cases of chronic bilateral pyelonephritis has led to the recognition of a number of complications and accessory factors that have been found to modify the usual course of this rather common disease. In a previous publication the significant symptoms and signs of the affection were described in some detail¹. The essential characteristics of this form of pyelonephritis consist in its bilateral occurrence, usually without demonstrable or evident obstruction to the outflow of urine². It is seen most frequently in young women between the ages of 15 and 30, but may occur in children or in older women. The youngest patient in this series among adults was 15 years of age, the oldest 55. The disease is usually of long duration. Symptoms of renal insufficiency may not appear for 10 or 15 years after the infection is first initiated. In seven of our patients the disease was known to have existed for at least five years or longer, and in three of them it had been present for from 14 to 17 years. During this long period leading up to the terminal stage, which manifests itself as protracted renal failure, the symptoms are usually slight and vague. Starting with a pyelitis in childhood, an infection of the urinary tract during pregnancy or, in rare instances, an outspoken acute pyonephritis there may be from time to time attacks of unexplained fever, with or without slight or fairly severe pain in the lumbar regions. These attacks are often accompanied by the passage of cloudy urine. Occasionally there is a history of albuminuria of many years' duration. Often there is a story of malnutrition, or sometimes of retarded growth in children, leading occasionally to rickety deformities. In some instances the progress of the disease is, for years, symptomless.

Unless the patient has symptoms or signs of renal failure, the condition is usually considered to be a chronic pyelitis. It is not until headache, nausea, vomiting, loss of weight, lassitude, dyspnea, or, in a few instances, convulsions, occur that the patient, in more or less desperate condition, is seen by a physician. Thirteen of our cases were not seen until the terminal stage of the disease was far advanced. Fourteen of these patients are known to have died, and in six of them the true nature of the disease was not recognized until autopsy which was obtained in 10 of the 12 cases.

It is possible however to determine the presence of the disease years before it is so far advanced. The signs that are of particular importance

* Received for publication April 27, 1937

are as follows. There is often slight pallor, a rather dry skin, and frequently a tendency to underweight. Edema is extremely rare, except when myocardial failure complicates the later stages of the disease. Unless hypertension supervenes, the heart is not enlarged. The blood pressure is not often elevated during the early stages of the disease. The systolic blood pressure was below 125 mm and the diastolic below 85 mm of Hg in five of nine cases which were seen at this period.

As the disease advances it is usual to find that the blood pressure rises. This is not, however, an invariable occurrence, for in at least three fatal cases the blood pressure remained essentially normal. In one woman of 21 the highest recorded blood pressure was 118 systolic and 68 diastolic, in a man of 24 the blood pressure varied between 120 systolic with 78 diastolic and 145 systolic with 75 diastolic, and in a boy of 15, the highest pressure was 140 systolic and 90 diastolic.

These instances should be recorded as exceptions rather than as exemplifying the rule, for usually the blood pressure rises during the latter months or years of the disease and may reach such high figures as 225 mm of Hg systolic and 150 mm Hg diastolic.

The retina usually show no changes until the disease is far advanced or has actually reached the terminal stage.

At times there is costo-vertebral tenderness. The urine is passed in fair quantities, the specific gravity is constantly low and with the progress of the disease becomes practically fixed at a figure near 1.010 or 1.012. The urine contains traces or moderate amounts of albumin, rarely casts or red blood cells, but many leukocytes which vary in numbers from time to time. In the great majority of patients cultures from the urine give at some time a growth of *B. coli*. In a few patients this organism was constantly present, but more often it appeared only at intervals. Though the early stages of the process may not be accompanied by any definite impairment of renal function, a striking feature is the unexpected frequency with which a marked impairment of renal function occurs at a time when the patient feels perfectly well. Months or even years before the terminal stage, the non-protein nitrogen of the blood may be distinctly elevated above normal, the phthalein output greatly reduced, and the curve of excretion flattened, the specific gravity of the urine fixed at a low level, and the urea clearance far below normal. In one patient who has been under observation for 7½ years, the non-protein nitrogen of the blood has never fallen below 42 mg per 100 c.c. and has at times reached 50 mg per 100 c.c., the specific gravity of the urine has been constantly fixed between 1.001 and 1.004, the phthalein output has gradually fallen from 60 per cent to 47 per cent, and the urea clearance from 42 per cent to 21 per cent of the normal standard. During all this time the patient, except for occasional headaches and attacks of lumbar pain, has felt well and been constantly at work. In another patient the non-protein nitrogen of the blood remained about 74 mg per 100 c.c. for three years before

death, and in a third patient, who has recently died, the non-protein nitrogen of the blood has varied between 55 mg per 100 c c and 88 mg per 100 c c for three years. During this protracted period of renal insufficiency there are rarely any of the symptoms that can be ascribed to this defect.

In some of these patients who display such long periods of renal insufficiency, the urine remains neutral or slightly alkaline. This may occur in the absence of evidences of cystitis and when the urine is sterile. In such

- Showing marked dilatation of ureters and pelves

patients it may, in fact, be impossible to produce an acid urine, either by the administration of ammonium chloride or by a ketogenic diet. This occurred in one of our patients who developed symptoms of acidosis, with a reduction of the CO_2 combining power of the serum to 29.6 volumes per cent, and still excreted urine which was alkaline or neutral in reaction.

One of the most important evidences of the disease is obtained by pyelography. The characteristic change observed in the pyelogram is a distortion, flattening and reduction in the size of the pelves (figure 1). This may occur without dilatation of the ureters, though in some instances there may be uniform or irregular dilatation of the ureters. An actual enlargement of the pelves of the kidneys is rare. The cystoscopic examination shows, as a rule, no changes in the bladder, though in one case ulceration of the mucosa was observed.

A combination of these various features produces a clinical picture which has such distinctive characters that one is usually able to recognize the disease, even though it occurs in patients who are apparently in excellent health.

The pathological changes in the kidneys which have been so frequently described^{3, 4, 5, 6} suggest that the progress of the disease is caused through the gradual destruction and elimination by inflammation and searing of small portions of the kidneys. The intervening parenchyma remains comparatively normal in appearance and apparently functions adequately. The kidney fails completely when this process of amputation reaches a point that is incompatible with life, or when a complication such as arteriolar sclerosis, or acute diffuse glomerular nephritis, is superimposed upon the renal structure that is already seriously damaged. Death may also occur from some intercurrent infection, but in all of our fatal cases uremia closed the picture.

It is of great importance to determine the exact manner in which the disease arises. In the majority of cases cultures of the urine and from the pelves of the kidney show a growth of *Bacillus coli*, and it is to be presumed this organism causes the original and the persistent infection. A gross inflammation of the mucous membranes of the bladder, such as commonly occurs in strictures of the urethra or prostatic hypertrophy is not present. There is rarely any evidence of gross strictures of the ureters though in cases of long duration points of narrowing, particularly in the portion that courses through the wall of the urinary bladder, may be present. It is in these cases that irregular dilatation of the ureters may be found. It is extremely difficult to determine, once the disease is well established, whether these anatomical strictures originally predisposed to an ascending infection of the urinary tract, or simply occur as a complication of the long continued passage of infected urine from the kidney. There is, however, considerable evidence to indicate that in infants and young children, so-called pyelitis is actually an acute pyonephritis, arising bilaterally from hematogenous infection of the kidneys. (Bugbee,⁷ Chown,⁸ Wilson and Schloss,⁹ Band, Dunlop, and Dick¹⁰)

It is very difficult to obtain definite information on this point in the adult, but the following cases seem to indicate that acute pyonephritis may occur in adults as a primary disease presumably from hematogenous infection of the kidneys by *Bacillus coli*, and further that recovery from the acute phase may be followed by intermittent pyuria due to *Bacillus coli*. The first case must exemplify a very unusual situation.

Case 1 (No. 18 in table). A young unmarried white girl, 16 years of age, was admitted to the Johns Hopkins Hospital on September 27, 1936, complaining of cramps in the stomach and dysentery. Her father had died of cancer of the rectum. For seven or eight years she has been subject to attacks of abdominal cramps which have come on every few months. They have lasted two to three days. Eight days before admission she had one of these attacks which was very severe. Three days after the onset of this attack her eyes had become swollen, and a day or two later her hands and feet were also swollen.

Physical examination showed a pale undernourished girl with temperature 100.6°, pulse 116, respirations 18. There was moderate anasarca, with swelling of face and pitting over shins. The fundi oculi showed increased shimmer of retina. Lungs were clear to percussion and auscultation. Heart was not enlarged and there were no murmurs. Blood pressure was 120 systolic and 85 diastolic. Abdomen was distended and tender. Liver, spleen, and kidneys were not palpable. Slight clubbing of the fingers was noted. Red blood cells 1,870,000, hemoglobin 39 per cent, white blood cells, 8,520, polymorphonuclear leukocytes, 60 per cent. Urine was acid, 1.010 specific gravity, there were large amounts of albumin—7 grams per liter, many granular and leukocytic casts, few red blood cells and great numbers of leukocytes. September 28, non-protein nitrogen of blood was 80 mg per cent, total plasma proteins 4.81 gm per cent, albumin globulin ratio 60/40. Blood culture made September 29 showed no growth. Culture of urine on September 30 showed growth of *Bacillus coli*. On this day a transfusion was given. October 2, phthalein excretion was 12 per cent in two hours, October 3, phthalein excretion was 24 per cent in two hours. Temperature remained elevated from September 27 to October 17. She continued to have severe abdominal cramps and diarrhea. On October 5, the non-protein nitrogen of blood was 76 mg per cent, and urea clearance 25 per cent of normal standard.

After October 5, there was some improvement. The edema diminished and finally disappeared by October 11. The albumin decreased to a small amount by October 9, but casts, red blood cells, and leukocytes continued in large numbers in the urine. There was rapid improvement in renal efficiency. By October 12 the non-protein nitrogen of the blood had decreased to 34 mg per cent, and on October 13, the phthalein was 72 per cent in two hours. By October 15 the non-protein nitrogen of the blood was 30 mg, and the urea clearance 64 per cent of maximum standard. Cultures from the urine continued to show heavy growth of *Bacillus coli*. At this time proctoscopic examination showed great numbers of polyps in the rectum and roentgen-ray of the colon demonstrated multiple polyposis, which was believed to explain the attacks of abdominal cramps and diarrhea that she had had for many years.

She was given ammonium chloride for a few days until the urine became sufficiently acid (pH 5.5), and, on October 18, 12 gm ammonium mandelate were administered daily for five days. By October 22 cultures of the urine showed no growth of *Bacillus coli*. Subsequently cultures from October 27 to November 2 were sterile. The albumin, red blood cells, and leukocytes rapidly diminished in the urine. For a few days the casts increased. November 2 to 6 the urine contained either traces of albumin or no albumin, occasional leukocytes, no red blood cells, and occasional hyaline casts. On November 29 the phthalein was 93 per cent. November 10 Hemoglobin 80 per cent, red blood cells 4,070,000. Since this time, as the chart (chart 1) shows, there have been recurrences of the bacilluria, controlled temporarily by the use of ammonium mandelate. Pyelograms made in March 1937 showed no abnormalities (figure 1 E).

It seems evident that this girl was suffering from an acute pyonephritis due to *Bacillus coli*. The renal infection was possibly hematogenous and secondary to an inflammation of the colon associated with multiple polyposis. Rapid sterilization of the urine and complete recovery from the acute pyonephritis followed the administration of ammonium mandelate, but subsequent cultures from the urine have given at intervals a growth of *Bacillus coli* indicating that the infection of the kidneys has not been eradicated. This patient not only illustrates one mode of origin of chronic pyelonephritis, but exemplifies in a striking manner the immediate benefit derived from the

CHART 1 (Case 1 text) showing course of illness of F.K. from September 1936 to April 1937

use of ammonium mandelate in infections of the urinary tract by *Bacillus coli*

Though it seems probable that this mode of onset may account for the origin of the disease in many, if not the majority of cases of this type of bilateral pyelonephritis, it is quite possible that some form of obstruction to both ureters may predispose the kidneys to infection. The enlarged uterus of pregnancy might act in this manner. In rare instances, congenital stricture or unexplained bilateral dilatation of the ureters, such as has been described by Ellis and Evans,¹¹ might produce the same result. The following case may be an example of this latter condition.

Case 2 (No 20 in Table) A white married man, 29 years of age, was admitted to the Urological Service of the Johns Hopkins Hospital on June 24, 1936 (For the early records I am indebted to Dr H H Young.) He complained of "kidney pain." He came of a healthy family and had usually been well. He could not recall any past illnesses except measles and mumps as a child. There had been no urinary disturbances. Married eight years, his wife had had no miscarriages, he denied any venereal infection. While in perfect health he suddenly developed pain in the epigastrium and both kidney regions nine weeks before admission (May 1936). The attacks were repeated but did not prevent his working. He soon developed jaundice, lost appetite, was nauseated and vomited. Jaundice lasted about two weeks and as it disappeared he improved, but attacks of pain persisted. Two weeks before admission (about June 10, 1936) pains became particularly severe, his temperature rose to 103° and he went to bed. Nocturia appeared without dysuria. He had chills and fever, and the pain became worse.

On admission his temperature was 102° F, blood pressure 195 systolic and 112 diastolic, pulse 72. He was somewhat undernourished. There was no edema. Lungs were clear to percussion and auscultation, the heart was not enlarged, the PMI was 7.5 cm to left of midline in the fourth interspace. There were no murmurs. There was tenderness in the costo-vertebral angles, over the kidneys, and to the left and below the umbilicus. Liver edge was readily palpable, spleen not felt. The prostate was small and not tender. Hemoglobin was 94 per cent, leukocytes 12,500. The urine was acid, amber, sp gr 1.020, no sugar, albumin 2+, no casts, rare red blood cells. Wassermann reaction was positive. On June 25, phthalein excretion was 89 per cent, non-protein nitrogen of the blood 60 mg per 100 cc. Culture of the blood showed less than one colony per cc of *Bacillus coli*, culture of the urine showed *Bacillus coli*.

An irregular temperature persisted with continuation of the pain. By June 26 blood pressure had fallen to 128 systolic and 70 diastolic, blood urea 32 mg per 100 cc. The urine continued to show small amounts of albumin and pus, but only occasional casts. Blood cultures made on July 1, 3, and 5 showed no growth. Cystoscopic examination showed no abnormality of the bladder, the ureters could be readily catheterized, cultures of urine from both ureters showed *Bacillus coli*. Phthalein appeared in the urine from both ureters in five minutes, 25 per cent was excreted from the left and 35 per cent from the right in 30 minutes. Ureteral catheters were left in place. There was excellent drainage from both sides, but the patient continued to have chills and fever. Retrograde pyelograms on July 9 showed marked dilatation of the lower portions of both ureters with pelvis that appeared normal (figure 1 F). There were no calculi.

He was admitted to the Medical Wards on July 12, 1936. At this time the blood pressure was 120 systolic and 72 diastolic, he showed loss of weight and some anemia.

The hemoglobin was 76 per cent, red blood cells 3,600,000, but there was no increase in leukocytes, 8,000. There was still fever, and there was tenderness to deep pressure in both flanks. The urine was alkaline, sp. gr. 1.001, with traces of albumin and much pus, but no casts. There was fever with daily rises of temperature from 99.4° to 102.4°.

On July 13 the non-protein nitrogen was 25 mg. per 100 c.c., the CO₂ combining power of the serum 65.3 per cent, and a culture from the urine showed heavy growth of *Bacillus coli*. A culture from the blood gave no growth. The patient was placed on 3 grams of potassium iodide a day, and seven days later the temperature was lower, the fever disappearing after the twelfth day. He was discharged on July 29, 1936, but returned to the hospital on November 13, 1936, saying that he had received eight injections of arsphenamine and eight injections of bisinuth in the interval. He had felt well, working daily until three days before admission (November 10), when he experienced dull pain in the lumbar region and in the epigastrium, and felt chilly. The pain grew worse and he had chills, fever, sweats, and frequency of urination. On admission the temperature was 104°, pulse 92. The skin was dry, the lungs clear, the heart not abnormal, and the blood pressure 120 systolic and 60 diastolic. There was tenderness in the costo-vertebral angles and in both lumbar regions, the liver was palpable, the spleen not felt. There was no edema. The hemoglobin was 100 per cent, red blood cells 4,700,000, leukocytes 12,750. Urine was cloudy, pale, sp. gr. 1.007, acid, showed no albumin, no casts, but great numbers of leukocytes, cultures gave a heavy growth of *Bacillus coli*. November 14, non-protein nitrogen of the blood was 30 mg. per 100 c.c. November 15 phthalein excretion was 70 per cent in two hours. November 18, urea clearance was 68 per cent of normal standard. By November 17 temperature had fallen precipitately to normal, and traces of albumin and much pus appeared in the urine. In an effort to combat the urinary infection after a preliminary course of ammonium chloride (6 to 8 grams a day) from November 15 to November 21, when the required urinary acidity of at least pH 5.5 was obtained, ammonium mandelate was administered in doses of 12 grams a day from November 21 for 14 days without definite effect, for *Bacillus coli* was cultivated persistently from the urine from November 14 to December 9, five days after the course of ammonium mandelate. There was, however, gradual symptomatic improvement. On December 1, 1936, the non-protein nitrogen of the blood was 32 mg. per 100 c.c., the blood pressure 130 systolic and 80 diastolic, and on December 6 the phthalein excretion was 50 per cent in two hours. On December 10 cystoscopy showed a granular cystitis, the ureters could be readily catheterized, the ureteral orifices were dilated by bougie. Pyelograms made again on December 10 were similar to those obtained on July 9 and showed no abnormality of the pelves, but a dilatation of the ureters affecting particularly the lower portions (figure 1 F). On January 2, non-protein nitrogen of the blood was 32 mg. per 100 c.c. January 4, cultures from urine again showed *Bacillus coli*. Following a preliminary period of ammonium chloride a second course of ammonium mandelate was started on January 5, but this could not be completed for the patient left the hospital on January 9, 1937.

It seems more than probable that this case is illustrative of an acute pyonephritis arising from an hematogenous infection by *Bacillus coli* in a patient who was already the subject of an abnormality of the urinary tract consisting of bilateral dilatation of the ureters due perhaps to some congenital anomaly. It is impossible, however, to exclude the urinary tract as the primary seat of infection with an invasion of the blood subsequently by *Bacillus coli*.

The acute illness in this patient may be regarded as the onset of a serious

and perhaps progressive infection of the kidneys and renal pelves, for it has not, so far, been possible to eradicate the infecting organism

It has been pointed out that as the bilateral chronic pyelonephritis progresses there is a distinct tendency for the blood pressure to rise. The blood pressure was above 160 systolic and 105 diastolic in 10 of 15 patients who were observed during the advancing or terminal stages of the disease. In half of these the systolic pressure was 200 or over, and in 10 the diastolic pressure was between 110 and 150 mm of Hg. The gradual rise of blood pressure from comparatively normal levels (105/60 and 146/90), during the early stages, to high levels (200/118 and 162/102) in the later stages could actually be followed in two patients.

On the other hand, in seven cases, including the two patients referred to above who were observed during a comparatively early stage of the disease, only one showed a systolic blood pressure over 140 or a diastolic blood pressure over 85 (146/90). The highest systolic pressure in five of these patients was not above 120, or the diastolic pressure above 85, while in four the highest diastolic pressure was not above 80 mm of Hg. In one patient the highest blood pressure was 138 systolic and 78 diastolic.

Since the hypertension comes as one of the late manifestations of the disease, it is important to learn whether it is due to a complicating arteriolar disease or whether it is to be considered as an essential part of the clinical picture and is related directly to the failing renal function itself.

It is hardly possible to accept the latter suggestion without some reservations, for it was found that the blood pressure was within normal limits or only slightly increased in seven patients in whom the evidences of renal failure were pronounced as measured by the retention of non-protein nitrogen, the excretion of phthalein, or the urea clearance. Five of these patients died. In four the systolic pressure never rose above 145, and in one varied between 110 and 170. One patient is living and the fate of the other is unknown. Four of the fatal cases came to autopsy.

On the other hand, if one inquires into the combination of hypertension with hemorrhagic retinitis and arteriolar lesions of the fundus, it is found that the relationship is quite striking. Table 1 gives the results of this study. Dr. Arnold Rich has very kindly examined the organs of the cases that have come to autopsy, with special reference to the condition of the arterioles. It has, therefore, been possible to add the valuable information obtained from him to the study of Cases 5, 6, 7, 8, 9, 11, 15, and 16 (table 1).

It may be seen that in 11 of the 12 patients who showed any elevation of blood pressure above normal, pathological lesions in the arteries and arterioles of the retina were observed during life in all but one. The arteriolar disease was combined with hemorrhages in eight cases and with hemorrhages and exudates in four patients. On the other hand, in seven cases seen during the early stages of the disease when the blood pressure was

within normal limits, except in one patient when it was 140 systolic and 85 diastolic, the fundi were normal. In this one patient slight alterations were observed in the arterioles. In spite of the normal blood pressure and the normal appearance of the fundi oculi, the renal function was definitely impaired in four. In the seven patients seen during the latter stages of the disease, in whom the blood pressure was either within normal limits or only slightly elevated but in whom the renal function was markedly depressed, pathological changes were seen in the fundus in only three, in two of whom the pressure was slightly elevated.

It seems, therefore, that the ophthalmological picture of retinal arteriolar sclerosis and hemorrhagic retinitis is much more nearly related in these patients to the hypertension than to the presence or degree of renal insufficiency.

The results of the microscopical examinations of the organs at autopsy are as follows. All cases showed a marked and extensive pyelonephritis. In

no case, however, could Dr Rich find, in addition to the pyelonephritis, pronounced or extensive hyaline sclerosis of the arterioles of the kidneys or other organs such as the pancreas, adrenals, and intestines

In the four fatal cases (6, 8, 14, and 16) in which the blood pressure remained within normal limits or was only slightly elevated, sometimes only at intervals, the arterioles of the kidney, pancreas, adrenals and intestines appeared normal. In one case (14) there was a complicating and definite glomerular nephritis. In three cases in which hypertension was marked and was one of the outstanding features of the clinical course a few arterioles were found in the kidney, pancreas, adrenals and intestines which showed moderate hyaline sclerosis, but the lesions were almost minimal in extent. One of these patients showed extensive hemorrhagic retinitis with retinal exudates (Case 5, fundi). A second showed extensive hemorrhagic retinitis with pronounced lesions in the arterioles and the third presented well marked changes in the retinal arterioles, without hemorrhages, exudates or edema. Two patients (11 and 15), both with pronounced hypertension, showed in addition to the extensive pyelonephritis a diffuse and advanced glomerular nephritis with moderate to minimal hyaline sclerosis of the arterioles in the kidney, pancreas, and adrenals. One of these patients (11) was not observed to have retinitis though the retinal arteries showed abnormalities, the other (15) showed marked lesions of the retinal arterioles with fairly extensive terminal hemorrhagic and exudative retinitis.

One must conclude from a study of this short series of fatal cases that widespread and extensive arteriolar sclerosis did not occur. Scattered and sometimes minimal hyaline sclerosis of the arterioles of the kidney, pancreas and adrenal was found in five of the fatal cases who during life had markedly elevated blood pressures. In two of these cases there proved to be, in addition, a diffuse chronic glomerular nephritis. In the four cases in which hyaline sclerosis of the arterioles was not seen in sections of the organs, the blood pressure during life was within normal limits in one and only slightly elevated in the others. In one of these latter cases a diffuse chronic glomerular nephritis was found at autopsy (14).

It appears, therefore, that the hypertension which was found to exist in the terminal stages of the disease, or was observed to develop during the course of the disease in two patients, was not associated with pronounced arteriosclerosis of the vessels of the kidneys, or with widespread uniform involvement of the arterioles of other organs. In spite of the marked hypertension and the lesions in the fundi, which were present during life in several of these patients, the pathological lesions at autopsy were not as extensive as those usually observed in arteriosclerosis. Unfortunately the fundi were only examined histologically in one case. In this patient (Case 5) the blood pressure varied from 180 systolic and 150 diastolic to 225 systolic and 150 diastolic, there was cardiac hypertrophy with myocardial insufficiency as a terminal event. It was noted by the late Dr William H Wilmer that

the optic discs were swollen, the arteries narrow, tortuous and irregular, and that there were many hemorrhages and exudates in the choroid. The picture was considered by him to represent vascular sclerosis of the retinal and choroidal vessels. This histological examination of the retina was made of several sections cut at different levels through both orbits. They showed that there was edema of the nerve head with several hyaline arterioles in the nerve head. There were no hyaline arterioles in the retina, no hemorrhages or exudates, but several small scars which may have been the result of organized hemorrhages or exudates. Such marked incompatibilities are certainly not usual, and it is difficult to understand why abnormalities during life, which are, as a rule associated with arteriosclerosis should prove, at autopsy, to be accompanied with so few anatomical lesions.

Unfortunately lumbar puncture was not performed in these patients and no information is available, therefore, concerning the pressures in the spinal fluid. In view of Pickering's¹² observations upon the association of albuminuric retinitis with high spinal fluid pressures, it would have been valuable to have data upon this point.

It was often noted that the height of both the systolic and diastolic blood pressures changed considerably from time to time in many of these patients. In Case 9 there were variations from 160/100 to 230/140, in Case 12 from 140/80 to 180/120, in Case 13 from 138/90 to 170/110, and in Case 16 from 110/80 to 170/110. Although this is not uncommon in some instances of arteriosclerosis it is observed more often in patients who are suffering from the form of hypertension generally designated as essential. It is also to be remarked that retinal hemorrhages were much more common (8 cases) than exudates (4 cases), and that swelling of the optic disc, though frequent (9 cases), was rarely marked.

One might therefore conceive of the condition as being somewhat different from the classical forms of arteriolar disease. Although it is impossible to correlate satisfactorily the elevation of blood pressure with the presence or intensity of renal insufficiency, it is to be noted that retinal hemorrhages and exudates were only found in those patients who showed evidences of marked renal impairment.

The experimental work of Goldblatt and his coworkers¹³ has shown that ischemia of the renal tissues of dogs and monkeys¹⁴ produced by reducing the arterial flow of blood to the kidney through constriction of the renal arteries, results in a persistent elevation of blood pressure. Even constriction of the arterial flow to one kidney may, and usually does, result in a definite increase in blood pressure, though the rise is much greater and of longer duration when both renal arteries are constricted.

This work has been amply confirmed by Page,¹⁵ Elaut¹⁶ and by Wood and Cash.¹⁷ Page has shown that denervation of the pedicle of the kidneys does not prevent the rise of blood pressure following the Goldblatt operation, and Goldblatt¹³ reports that excision of the dorsal sympathetic ganglia and splanchnic nerves does not reduce the blood pressure in his dogs.

The experiments of Tigeistedt and Bergman¹⁸ upon the presence of a pressor substance in the kidneys of rabbits designated by them "Renin" have been repeated and modified by Harrison, Blalock, and Mason,¹⁹ and by Prinzmetal and Friedman²⁰. The former authors found that extracts of the kidneys of normal dogs usually produced moderate transient increases in blood pressure when injected intravenously into unanesthetized dogs, but that extracts of kidneys from dogs made hypertensive either by ligation of the ureters or by the Goldblatt method produced a much greater rise in pressure than the extracts from normal kidneys. Prinzmetal and Friedman not only compared the extracts from the two kidneys of dogs, after one renal artery had been constricted with resulting hypertension, but compared the effects of extracts from the kidneys of patients who had died with benign and malignant hypertension, chronic glomerular nephritis, and from chronic pyelonephritis with extracts of normal human kidneys. It was found that the extracts of the abnormal kidneys from both dogs and human beings were usually much more potent in their ability to raise the blood pressure when injected intravenously into dogs than the extracts of normal kidneys.

It is not understood how renal ischemia or the injection of extracts of diseased kidneys cause hypertension, but the results suggest that the pressor substance present normally in the extract from the cortex of the healthy kidney is much increased in the diseased kidney. Whether these experiments and observations have any bearing on the hypertension developing during the later stages of chronic pyelonephritis with contracted kidney it is not possible to say, but there are analogies which are highly suggestive in the two sets of conditions.

It is a matter of particular interest that constriction of only one renal artery in dogs will result in a moderate degree of hypertension which may persist for some time. Both Jacoby⁵ and Haslinger⁴ report instances of unilateral "Schlumpfiere" due to chronic pyelonephritis and the condition does not seem to be extremely rare. It may occur in individuals in whom a chronic infection of the kidney occurs in relation to a renal calculus imbedded in one of the calyces of the kidneys. One such case has come under my observation. In this patient the unilateral pyelonephritis was associated with hypertension. The blood pressure varied from 210/120 to 140/100. There was no evidence of renal insufficiency for the phthalein excretion was 90 per cent in two hours, the non-protein nitrogen of the blood 30 mg per cent, the urea clearance 63 per cent of the normal standard, while the specific gravity of the urine varied from 1.006 to 1.030. The question naturally arises, however, as to whether disease, such as this, of one kidney could produce a persistent elevation of blood pressure in man.

CONCLUSIONS

The contracted kidney of chronic pyelonephritis may arise in adults, as it is said to arise in infants and children, from a hematogenous infection of

the kidneys. The bacterium which is usually responsible for this infection is *Bacillus coli*.

The onset of the disease may assume the form of acute pyonephritis.

The disease progresses insidiously for years but may be recognized in many patients during this insidious stage by special methods of examination.

During the latter phases, the chronic renal insufficiency is often, but not always, combined with intermittent or persistent hypertension.

Hemorrhagic retinitis occasionally with exudates may occur at this time.

The hypertension was not associated with pronounced or extensive arteriosclerosis in nine fatal cases which came to autopsy, for among six of these patients who had an elevated blood pressure during life only five showed any arteriosclerosis at autopsy, and in two of these it was minimal in degree and in extent. In three of the fatal cases the chronic pyelonephritis was combined with a chronic diffuse glomerular nephritis.

The explanation for the hypertension occurring particularly during the latter stages of the contracted kidney of pyelonephritis is not clear.

PRIMARY INFLAMMATION OF ARTERIES

By HOWARD T. KARSNER, M.D., F.A.C.P., *Cleveland, Ohio*

ARTERIES may become inflamed because of the extension of neighboring inflammations or because of the action of bacteria or parasites brought to the site from some more or less remote portal of entry. The disease is due to the presence of the infective agents and their products. There are other forms of arteritis which appear to be independent of the immediate presence of infectious organisms. Ultimately both these forms of arteritis are probably due to the products of the organisms, but there is at least an academic difference between those in which bacteria are found in the inflamed focus and those in which they are not. Similar lesions are found without known infection in the body. Furthermore, there are some in which hyperergic phenomena seem to play an important part. It is proposed to apply the term secondary arteritis to those in which infective agents are present and the term primary arteritis to those in which these agents are not demonstrable.

Vascular changes in acute infectious diseases have been extensively studied and much of the pertinent literature is reviewed by Karsner and Bayless. Degenerative and mild or severe inflammatory lesions of the arteries, not directly caused by an infective agent, are well known, but few if any correlative studies have been published. The original account of periarteritis nodosa by Rokitsansky in 1852, correlated with the clinical aspects by Kussmaul and Meier in 1866, has been followed by many publications on arterial inflammations, in which the term has been employed to designate several varieties of necrotizing and exudative arteritis. Critical examination of several reports shows that what is called periarteritis nodosa by the authors does not fit even the imperfectly known clinical or pathological characters of the disease. The confusion is recognized by Klinger, Arkin and others who have suggested distinguishing features. This report is a further attempt at clarification. The arterial diseases described below have been found sometimes in single organs or parts, sometimes in a few separate situations and sometimes widely distributed. In this study attention is directed particularly to small arteries of different size, generally with an outside diameter of something in the order of 100 to 500 micra and not

* Reported in abstract before the meeting of The American Association of Pathologists and Bacteriologists, April 10, 1936 (*Am. Jr. Path.*, 1936, **xii**, 740).

From The Institute of Pathology, Western Reserve University and University Hospitals, Cleveland, Ohio.

Aided by a grant from the Josiah Macy, Jr. Foundation.

† In the literature the terms necrosing and necrotizing are used interchangeably. The latter has become customary in this laboratory.

including arterioles with an outside diameter of 50 micra or less. The inflammations occupy usually only a comparatively short segment of the vessel. They do not frequently extend to the arterioles and if they do, they involve only the proximal part of the arteriole.

In order to facilitate discussion, a classification is desirable and the following scheme is suggested:

ARTERITIS

Acute

Alterative (degenerative)

Necrotizing

Exudative

Vegetative (thrombo-arteritis)

Proliferative

Organizing

Chronic—combinations of

Intimal

Medial

Adventitial

Acute Alterative (Degenerative) Arteritis. The simpler retrogressive changes are found principally in the form of intracellular and intercellular edema. Lesions of this sort were described as early as 1869 by Hayem as an accompaniment of infectious diseases. The intima may show swelling not only of the endothelial lining cells but also those of the sub-endothelial

FIG. 1. Edema of media, observed as a vacuole at one pole of section, together with granularity of cytoplasm and almost complete disappearance of medial nuclei. Acute degeneration. Male, aged 5 years, rheumatic fever. ($\times 500$)

tissues in arteries of sufficient size to have this layer. Intercellular accumulations are not frequent but may be observed, especially in rheumatic fever. The media may show the same forms of disease. So-called *chromotropic* degeneration is found much more often in the media than in the intima. It differs from simple edema in that it stains somewhat as does connective tissue mucoid, but is probably primarily edematous in character. Changes in the elastic laminae include swelling, splitting and fragmentation. The justification for regarding these degenerative lesions as inflammatory lies not in the fact that they invariably show associated exudative or proliferative phenomena, but rather in that they exhibit these changes as the disease progresses. This progression is indicated by comparison of a large number of specimens rather than by directly observed sequences.

In addition to the infectious diseases, vascular edema has been observed in neo-arsphenamine poisoning (Christianson), in experimental allergy (Murasawa, and Kaiserling and Ochse) following partial denervation (Kerper and Collier), as the result of repeated grafting of adrenals (Leriche and Froehlich), and as a result of prolonged life in compressed air (Smith, et al). Both edema and chromotropic change are common in *periarteritis nodosa*.

FIG 2 Acute necrotizing arteritis in kidney. Unexplained acute diffuse arterial disease. Female, aged 19 years. ($\times 194$)

Acute Necrotizing Arteritis Except where a lesion is found in arteries which are so small that they approach arteriolar size, necrosis generally is first seen in the media. It may occur as an isolated area but usually involves the entire circumference of the artery in a given segment. Confluence of cells, coarse granularity or hyalinization of cytoplasm and complete dis-

appearance of nuclei usually characterize the necrosis. With the exception of minute arteries, pyknosis and karyorrhexis are only occasionally present. Necrosis often extends to involve the intima and adventitia, but except for the smallest arteries is rarely primary in those coats. In contrast to the simpler degenerative lesions, exudation is constant when necrosis is found. The proportions of the cells of the exudate vary, sometimes they are principally lymphocytes and sometimes the polymorphonuclear leukocytes predominate. Lesions of this sort are observed in experimental anaphylaxis or allergic states (Kaiserling and Ochse, Ssolowjew and Ariel, Eickhoff), as the result of injections of trypan blue (Pfuhl), following injections of specific antisera (Matsugi et al), in the Schwartzman phenomenon (Karsner and Moritz), following injections of allylamine (Mellon, Baker and McElroy), and other procedures. In man the necrotizing lesions are occasionally found in infectious diseases, especially those with septicemia, they occur in rheumatic fever and are well shown in the skin of erythema induratum.

FIG 3 Acute exudative arteritis, with hemorrhage. Erythema induratum. Female, aged 19 years. ($\times 194$)

Acute Exudative Arteritis The term exudative includes both cellular and fluid exudation. The fluid can be determined to be exudative anatomically only by the presence of fibrin. Cellular exudation may be present without deposition of fibrin and if both be present the cellular component predominates, but occasionally the fibrin may form a conspicuous part of the exudate. Lesions of this sort are found especially in secondary arteritis, but are not infrequent among the primary forms. Exudation accompanies other changes such as degeneration, necrosis and cellular pro-

liferation. It occurs in a wide variety of conditions including some of the cases of rheumatic fever. The combination of necrosis and exudation, a necrotizing-exudative arteritis, characterizes the acute stages of periarteritis nodosa and occurs in the conditions noted in the preceding paragraph.

Acute Vegetative (Thrombo-) Arteritis. Although it may be true, as claimed by Nygaard and Brown, that thrombosis can occur without disease of the intima or other coats of the vessel, the deposit of thrombi usually follows other arterial lesions. Thrombosis is common to the more severe arterial inflammations and also occurs in arteries where the inflammation

FIG. 4. Acute vegetative arteritis. Thrombus attached to wall of a large coronary artery. No bacteria. Male, aged 24 years. Rheumatic fever. ($\times 226$)

or degeneration can be identified anatomically only as the result of careful study. The deposit of fibrin may start in the intima or upon the intima and may be of focal form, resembling vegetations, or occlusive. Other phenomena of inflammation are frequently found. The resemblance of this form of arterial disease to endocarditis has been emphasized by Baehr, Gross, Bender, Matsugi and others. It would appear that in the arteries as in the endocardium, the primary lesion is subintimal and the thrombus formation secondary. In those cases in which endocardial disease is present, there may be emboli into the arteries, but thrombo-arteritis occurs without associated endocarditis and can be considered to be an independent phenomenon. In some instances it may be due to deposit of bacteria from the blood stream, a secondary inflammation, but that primary forms exist is confirmed by their occurrence in patients without bacteremia and without demonstrable bacteria in the thrombus.

Acute Proliferative Arteritis Proliferation of cells in acute arteritis is observed almost solely in the intima. There are cases in which this is undoubtedly a proliferation of endothelial cells. In many, however, masses of swollen mononuclear cells with poorly staining cytoplasm, of uncertain origin, form masses piled up into the lumen of the artery. Thrombosis is not found except as a later manifestation and exudative cells are found not so noticeably in the intima as in the adventitia. Even in the latter situation, exudation may be scanty. Intimal proliferation is seen in many varieties of arteritis such as that observed in rheumatic fever, in syphilis and cases of more or less localized arteritis without known cause. It is reported

FIG. 5 Acute proliferative arteritis. Disease localized to region of gall-bladder and kidney. Female, aged 35 years. ($\times 190$)

by Wiese in pulmonary thrombo-arteritis, by Leriche and Froehlich in the arteritis following adrenal grafting, and by Kaunitz and by Yater and Cahill in ergotism. It may be found sometimes in periarteritis nodosa. It is reasonable to assume that as endothelial proliferation in glomerular capillaries signifies an inflammatory reaction, this lesion of arteries may be similarly interpreted. Proliferation of medial connective tissue cells, of fibroblastic type, as an indication of acute reaction is uncommon but may be found, especially in the florid stages of rheumatic fever.

Organizing Arteritis This is observed as a later stage of arteritis, particularly that which has been associated with thrombosis. The character

of the granulation tissue is not different from that observed elsewhere, except that as organization proceeds it is likely to be accompanied by canalization. Buerger considers the later vascular lesions of thromboangitis obliterans to be an organizing stage of a previous acute thrombo-arteritis.

FIG 6 Organizing acute arteritis. Epicardial artery of a case of periarthritis nodosa. Female, aged 26 years. ($\times 300$)

Wiese describes it in primary pulmonary thrombo-arteritis. It is well seen in periarthritis nodosa and in other diseases where survival permits of organization.

Chronic Arteritis In this category are included progressive fibrotic disease of arteries, which do not show the lipoidosis, atheroma or calcification of arteriosclerosis. This differentiation cannot be considered inflexible because any dense fibrous mass may finally become fatty and calcified. That it is progressive, as required by definition of chronic inflammation, is assumed by the variation in the appearance in different arteries from the same patient. Only occasionally does it show lymphocytic infiltration. It differs from endarteritis obliterans, intimal arteriosclerosis and the senile medial disease of Monckeberg in that it involves two or more coats and when it occurs in the media is irregularly distributed and does not show calcification. It is particularly well illustrated in rheumatic fever, where the chronic arterial lesion resembles the chronic endocarditis. It occurs in

thromboangitis obliterans It is seen in the smaller arteries, such as the vasa vasorum in syphilis That this form of syphilitic disease is due to the direct action of spirochetes is doubtful, because they are not demonstrable in the lesion

On the basis of a single preparation it is often impossible to distinguish chronic arterial inflammation from involutional changes such as are observed in the senile uterus, ovary and other situations The same may be true of destructive and reparative phenomena in such lesions as chronic cholecystitis These difficulties are ameliorated if specimens from many parts of the body be available for study

DISCUSSION

The material upon which this classification is based was from patients who presented a wide variety of clinical manifestations Extensive acute arteritis may express itself with fever, leukocytosis, purpura and similar general phenomena If localized, as for example in the gall-bladder, kidney or appendix, etc (Plaut), the clinical features disclose the localization and general signs depend upon the severity of the disease As with arteriosclerosis of medium sized and small arteries, the immediate effects of acute arterial inflammations are referable to the effects within the parts diseased, but acute arteritis differs in that it presents more or less marked signs and symptoms of a general disease In one case of acute proliferative arteritis of kidney and perirenal structures, surgical removal of the diseased tissues resulted in apparently complete recovery as long as the patient could be traced (four years) In contrast, a case of chorea in a child resulted in death in a few weeks with widespread acute exudative arteritis, of rheumatic character Chronic arteritis is without accompanying clinical signs unless it be of sufficient degree to produce local atrophy and fibrosis with resultant physiological change, as is also true of arteriosclerosis These statements are in accord with the distribution and character of the lesions as outlined in the introductory paragraphs

The acute lesions described rarely occur as pure forms The combination of necrosis and exudation is worthy of special comment because this is the lesion seen most often in periarteritis nodosa In the typical cases the cells of the exudate include eosinophiles, both polymorphonuclear and mononuclear Aikin did not consider the eosinophile as an essential feature Middleton and McCarter mention eosinophilia of the circulating blood but do not emphasize eosinophiles in the exudate There is no mention of these cells in the reports of Bennett and Levine, of Yardumian and Cohen, or of Krahulik, Rosenthal and Loughlin Friedberg and Gross note the eosinophiles in one of their four cases and Curtis and Coffey, Bernstein and also Dungal in each of their cases Gruber, who suggested discontinuous hyperergic phenomena as the cause of the disease, paid little or no attention to eosinophiles, whereas Kline and Young suggest that the local eosinophilia

supports the hypothesis of allergic causes. Certainly a necrotizing-exudative arteritis occurs both in man and experimental animals without the general manifestations of periarteritis nodosa. While it would perhaps be too stringent to insist upon the finding of eosinophiles to establish the diagnosis, the local eosinophilia should be given a place of great importance. As emphasized by Klemperer, there are other features of significance if the original meaning of the term periarteritis nodosa is to be preserved, as for example, the presence of nodules visible to the naked eye or through the hand lens as well as the microscopic demonstration of aneurysms. With the criteria suggested, it should be possible to avoid the conclusion that a wide variety of acute arterial inflammations belong in the category of periarteritis nodosa.

Syphilitic disease of smaller arteries, especially those of the meninges, is characteristically exudative and necrotizing. Because spirochetes have not been found in the lesion (Spielmeyer), it has been thought to be due to "toxins." In a recent case observed in this department, spirochetes were found in abundance. Thus, this form of syphilitic arterial disease belongs in the proposed category of secondary arteritis, as is true of tuberculous arteritis and other forms, as for example that seen in typhus fever, hog cholera, brucellosis, etc.

In human material, involvement in variable degree of all the coats of the artery is usually found, although often the lesion is especially conspicuous in one or another of these layers. Thus it might be assumed that the inflammation begins in the entire wall as a unit. That this assumption is probably not valid is indicated by the experiments of Ramsey and her co-workers, who found that chemical, particulate or bacterial injury of the intima is first reflected in reaction in the perivascular tissues (adventitia and surrounding connective tissue) or the outer portions of the media. Exudation then extends through the media, appears to be temporarily hindered by the internal elastic lamina, but soon involves the entire wall. Thus it would be unwise to suppose that because a section of artery shows a given lesion to be especially prominent in one coat, that coat is the one primarily affected. The course and sequences of arteritis deserve extensive and detailed study.

SUMMARY

In addition to those inflammations of arteries of small and medium size due to extension of local inflammation or direct invasion of bacteria and other organisms, which may be designated as secondary arteritis, there are forms of arteritis due to unknown or ill-defined causes which can appropriately be named primary arteritis. The lesions found in these primary forms have been classified and include both acute and chronic varieties, the former varying from degenerative and necrotizing to exudative, proliferative and organizing forms. The chronic forms differ from arteriosclerosis in distribution of fibrosis in the three coats of the arteries and by delayed or ab-

sent secondary changes in the fibrous tissue. It is suggested that an improved nomenclature for the varieties of arteritis will aid in correlating descriptive morphological and clinical data so that a precise understanding of these diseases will be attained.

HEALED BACTERIAL ENDOCARDITIS

By LOUIS HAMMAN, F A C P, *Baltimore, Maryland*

IF we base our views about the course of subacute bacterial endocarditis solely upon routine observations made in the clinic, we must conclude that it is an exceptionally malignant disease, for almost invariably it ends in death. Reckoned from the time symptoms first appear the average duration of the illness is about six months and only seldom does the affected patient live longer than a year. In 1924 Thayer reported that of 206 cases, collected from the records of the Johns Hopkins Hospital, none had recovered. As far as I know the uniform mortality of the disease at that hospital has not changed during the past 12 years, for I am convinced that had a recovery occurred, this exceptional event would have been loudly proclaimed, and could not have escaped my notice. Certain I am, that no well-established instance of subacute bacterial endocarditis, which has been under my observation, has ever recovered. This depressing experience is by no means unusual, for many seasoned practitioners tell me that their results have been precisely the same. I think it is true that when the diagnosis of endocarditis lenta is securely made then most physicians regard the outcome as hopeless.

Nevertheless, in spite of this almost universal pessimism, it cannot be doubted that occasionally recovery does occur. However, not so frequently as is reported in the literature, for a careful examination of these reports reveals that in many the diagnosis has not been conclusively established. In some the blood cultures have been sterile, in others the evidence of an endocardial lesion is unconvincing, in still others the facts are so incompletely reported that it is impossible to identify the true nature of the illness. Many competent observers in discussions and under other circumstances merely state that in their experience so many patients have recovered without giving any clinical details. Knowing the established reputation of these physicians one cannot doubt the accuracy of their statements even in the absence of supporting facts. However, leaving all these reports aside, we may still find detailed and convincing accounts of many cures. I do not pretend to name them all but choose as illustrations those instances reported by Murray, Hemsted, Capps, Bogendorfer, Schottmuller, Perry, Kissing, and Kraiss.

I have omitted from this list the name of Libman because his reports contrast so violently with general experience that they must be noticed separately. Libman reports at least 3 per cent of recoveries in the usual

* Presented at the St. Louis meeting of the American College of Physicians, April 20, 1937.

type of the disease and is convinced that many more recoveries occur in mild cases which are often overlooked. He publishes brief notes of 17 recovered cases, some dying in a second or even third attack after intervals of many years. I must admit that Libman's results are more in accord with evidence obtained post mortem than are the usual results of other physicians. This is strong corroboration of the truth of his observations, if, indeed, any corroboration is needed for the observations of so distinguished a student in this field. Therefore it is interesting to ask what may be the reason for the divergence of these results.

The characteristic clinical symptoms of subacute bacterial endocarditis are fever, anemia, evidence of a valvular defect or a congenital abnormality, splenic enlargement and embolic phenomena. When these symptoms are well developed the diagnosis is assured. However, very often one or more of the symptoms is absent and then the diagnosis may be difficult. For instance, when there are no embolic phenomena, the disease, in its mild forms, may very closely resemble rheumatic fever. Indeed, often it is impossible to distinguish confidently between them. It is unnecessary to remind you how very difficult it is at times, even in the presence of loud murmurs, to be sure that there is an endocardial lesion, and yet without this confidence one can only surmise, but never state, that the patient has bacterial endocarditis.

The diagnosis of bacterial endocarditis can be made without actually demonstrating the presence of bacteria in the blood stream although this demonstration is always desirable and under circumstances, when the complete clinical picture is not developed, it is essential. However, it must be emphasized again and again that the mere presence of bacteria in the blood stream, when other characteristic symptoms, especially the undoubted presence of an endocardial lesion, are absent, does not warrant the diagnosis of subacute bacterial endocarditis. On many occasions pyogenic organisms gain access to the circulating blood but do not settle within the heart and the presence, say, of staphylococci in blood cultures and of a systolic murmur over the heart does not justify the diagnosis of bacterial endocarditis, especially not, if the observer reports that an examination made months later, when the patient had recovered, demonstrated the heart to be normal. It is now common knowledge that the *Streptococcus viridans*, the organism most often concerned in subacute bacterial endocarditis, frequently invades the blood stream when there is infection in the upper respiratory tract and no doubt less frequently with infections located elsewhere. Therefore, the presence of bacteria in the blood during the course of a febrile reaction does not signify that the endocardium has become infected, unless at the same time there is undisputed evidence of a valvular lesion or a congenital defect, and other characteristic symptoms of bacterial endocarditis are present.

Whether the remarkable groups of cases reported by Oille, Graham and Detweiler, of Toronto, and by Salus, of Prague, are real instances of

Streptococcus viridans endocarditis or instances of bacteremia without endocarditis is difficult to decide. Certainly, their experience is unique, and I can only say for myself, that to me the evidence upon which is based the diagnosis of endocarditis is unconvincing. Oille, Graham and Detweiler report an epidemic of 23 cases, mostly in children, observed during a period of six months. The constitutional symptoms were mild, fever slight or absent, there were no embolic phenomena, all recovered. The evidence of endocardial involvement consisted almost entirely of apical and aortic systolic murmurs. Only three showed slight enlargement of the heart. Blood cultures in all were positive for *Streptococcus viridans* but only one culture was taken in 17 of the cases. These results contrast with the report of Warren and Herrick who collected from the records of the Roosevelt Hospital 134 cases with positive blood cultures. In 40 the infecting organism was the *Streptococcus viridans*. Twenty-five of the 40 had endocarditis, of these 22 had died, three were still living but unimproved. Of the remaining 15 cases, without endocarditis, 10 had recovered.

It is reasonable to assume that instances of bacterial endocarditis with very mild clinical symptoms are the ones which have the best chance of recovery. Moreover, this assumption is strongly supported by postmortem observations. However, it is these mild cases which are particularly difficult to recognize. Often there is but little fever, anemia, though always present, may be slight, and appreciable splenic enlargement and embolic phenomena may be absent. Usually they are regarded as instances of rheumatic or syphilitic heart disease and the autopsy revelation, demonstrating bacterial endocarditis, comes as a great surprise. With experience, the diagnosis of bacterial endocarditis may often be proposed under these circumstances, but cannot definitely be made, unless cultures demonstrate repeatedly the presence of bacteria in the blood. Unfortunately, in these mild cases, only a small number of bacteria may be washed into the blood stream and undoubtedly, sometimes, they are present there only intermittently. Therefore, to recover them cultures must be made repeatedly and with great care. I cannot say to what degree technical skill in bacteriology may improve the diagnosis of these mild cases. As regards the gonococcus I am sure that success in cultivating it from the blood stream depends in large measure upon the experience and skill of the investigator. The gonococcus is often the infective agent in these mild cases of bacterial endocarditis and yet, although it is usually recovered from fulminating cases of the disease, it is very seldom demonstrated in the mild cases. Nevertheless, the conditions found at autopsy indicate plainly that during life many bacteria must have been discharged into the blood stream. As regards the *Streptococcus viridans* there is not the same difficulty in growing it. The methods are now standardized and with reasonable care should give uniform results. However, it is always possible that extraordinary care may be more often successful. It is a matter worthy of consideration.

Let it be understood that nothing is further from my intention than to explain, as due alone to imperfect or faulty technic, the well-known fact that it is usually difficult and often impossible to grow bacteria from the blood of patients with mild and protracted symptoms of bacterial endocarditis, even when the conditions found at autopsy demonstrate clearly that large numbers of bacteria, constantly or intermittently, must have escaped into the blood stream. As I have already remarked it is usually a very simple matter to recover bacteria from the blood of patients acutely ill. The difficulty arises only when the disease is mild and of long duration. This difference, I think, must depend chiefly upon the gradual development of immunological forces. When, with the passage of time, the body acquires a powerful system of defense, then, although bacteria are swept into the blood stream, they are immediately attacked and soon destroyed. There is abundant evidence of the efficiency of this mechanism. The very fact that suppuration so seldom occurs is difficult to explain upon any other assumption. Even when the infective agent is the *Staphylococcus aureus*, widely spread abscesses are seldom seen in subacute cases. Occasionally we are successful in growing organisms from the blood drawn by puncture from the brachial artery, whereas, repeated efforts to grow them from venous blood are unrewarded. Here we may suggest that many bacteria are removed from the blood during its passage through the capillaries, but it seems to me even more likely that the fact is due to the greater length of time allowed the forces of immunity to play upon the bacteria. The apparent contradiction that in the face of these destructive forces bacteria still grow freely upon the infected valves is explained simply by the location of the bacteria, a location which shields them safely from harm. If you will look upon the stained section of an infected valve you shall see that the bacteria are accumulated beneath the margin of the valve where no blood vessels penetrate, and where they are secure from the reach of injurious chemical substances in the blood which bathes the valve, and from attack by leukocytes which may settle upon its surface. From this sheltered home colonies wander out towards the base of the valve but they do not penetrate far, for when they reach the area supplied by blood vessels they quickly perish.

I can propose only three possible explanations for the unusual results which Libman reports. First, being especially interested and experienced in the diagnosis of bacterial endocarditis he recognizes many mild cases which would escape the notice of average observers. Second, he is more indefatigable in the search for bacteria in the blood stream. Third, his technical resources in bacteriology are superior to those of the average laboratory.

When now we turn from the clinical experience with bacterial endocarditis and regard the disease from the standpoint of the pathologist we shall see prognosis in a different light. I think the pathologist, entirely unacquainted with the clinical course of the disease, and basing his opinion

solely upon what he observes at the postmortem table, would be surprised to hear that very few patients recover. In all but the very acute cases he is accustomed to find unmistakable evidence of healing. In one case, although there are active vegetations along the margins of a valve, in other portions dense fibrosis and calcification show where previously active lesions have healed. In another case, the process is mildly active upon one valve, whereas, another valve is scarred and contracted showing no longer vegetations or bacteria. In still another case, there is scarring and calcification of one or more valves without the slightest remaining evidence of infection, only the scarred remnants of infection long past. In a word, he sees almost regularly a strong tendency to healing, not infrequently a state of affairs where healing has become nearly complete so that he remarks, "if the patient had lived a little longer surely he would have recovered", and occasionally only stiff fibrotic valves as evidence that a previous lesion has completely healed.

The object of this communication is to attempt to bring our clinical and pathological experience more nearly into accord. This has been done before, for instance, by Libman and by Weiss and Rhoads. Still I think the subject is worthy of repeated attention. Those who are accustomed to follow patients from the ward to the postmortem room soon become convinced that in the clinic they fail to recognize many cases of bacterial endocarditis, and, from the character of the lesions there observed, that many patients recover and then live on for years with the usual evidence of a valvular defect. To illustrate these facts I have selected a few recent observations.

CASE I

L. B., 29 years, female, colored, single

A colored housemaid, then 27 years of age, came to the Gynecological Clinic of the Out-Patient Department of the Johns Hopkins Hospital on February 9, 1932, complaining of pain in the abdomen and too frequent menstruation. The diagnosis was made of right-sided, chronic inflammatory pelvic disease and myomatous uterus. She returned to the Medical Clinic of the Out-Patient Department on January 30, 1933, complaining of palpitation of the heart and shortness of breath. Two days later she was admitted to the hospital. There she stated that she always had been well, except for the menstrual disorders for which she had gone to the Gynecological Clinic, until December 27, 1932, when she was taken during the night with severe pain about the umbilicus. Later she had pain on the left side of the chest which persisted for three days and then disappeared. This pain was severe and was increased by deep breathing. During the attack the patient had nausea and vomited on several occasions. When these symptoms came on the patient had had for some days a slight cold. After the attack of pain she had cough, with a little expectoration, which at times was spotted with blood. She was quite sure that she had had fever. After the attack she was up and about for a few days but she then began to notice that she was very short of breath and that the heart beat rapidly and forcefully on slight exertion. The shortness of breath grew steadily worse and soon she was unable to lie down in bed. After 10 days her symptoms improved somewhat and she tried to work, but immediately became so short of breath that she had to give it up. She then noticed that her ankles were swelling and that palpitation and weakness were growing more pronounced.

Examination Temperature, 100.2°, pulse, 102, respirations, 48, blood pressure, systolic 90, diastolic 60

The patient was a well-developed, poorly nourished colored woman, propped up in bed, breathing rapidly but not in great distress. There was no cyanosis and no edema other than a little pitting over the shins. She evidently had lost weight. The mucous membranes were rather pale. The eyes were normally prominent, extra-ocular movements well performed. Pupils were equal, reacted actively to light. The fundi showed no abnormality. The teeth were in poor condition with marked pyorrhea. The pharynx was slightly injected, the tonsils were enlarged and scarred. Glands at the angles of the jaw were somewhat enlarged. Otherwise there was no glandular enlargement. The thyroid was just palpable. Trachea was in the midline.

FIG 1 Heart of Case 1 For description see text

The chest was well formed and symmetrical. The lungs showed no abnormality other than a few moist râles at the right base. The heart was greatly enlarged. There was a diffuse forcible impulse all over the precordium. The apex beat was in the fifth interspace, 11 cm from the midline. At the apex the shock of the first sound could be felt and at the base the shock of the second pulmonary sound. At the apex there was also a presystolic thrill. The area of cardiac dullness measured 5½ cm to the right, and 12 cm to the left of the midline. At the apex the first sound was loud and booming in quality, it was immediately preceded by a short rumbling presystolic murmur, and was accompanied and followed by a loud, harsh systolic murmur, widely transmitted. It was well heard in the axilla and below the angle of the scapula in

back The second pulmonary sound was greatly accentuated Rhythm was irregular due to the occurrence of very numerous extrasystoles The pulse was soft, rapid and of small size The vessel walls were not thickened The abdomen was normal in appearance, the walls were soft and relaxed, no tenderness, no masses were felt The edge of the liver was 3 cm below the costal margin, it was slightly tender The spleen was not enlarged The pelvic examination revealed a myomatous uterus The rectal examination was negative The neurological examination was negative

Course in the Hospital After a period of rest with digitalis, the patient rapidly improved and at the end of six weeks was up and about the ward in comfort

Laboratory Examinations

Blood Count 2/1/33 Hgb 54 per cent, R B C 3,550,000, W B C 8,900
3/18/33 Hgb 72 per cent, R B C 4,700,000, W B C 9,600

Wassermann reaction was strongly positive

Blood Culture 2/10/33 No growth

Lumbar Puncture 3/7/33 10 cc clear, colorless fluid withdrawn No evidence of increased pressure No cells Pandy negative Wassermann reaction negative Colloidal mastic test negative

Urine Specific gravity varied from 1.014 to 1.030 Occasionally there was a trace of albumin but usually none The sediment contained a few pus and epithelial cells

The temperature on admission varied from 99° to 100.4° On February 23 it rose to 102° following the extraction of an infected tooth Subsequently it fell again, ranging between 98.6° and 100°

The pulse rate varied from 70 to 110

Roentgenogram 2/2/33 Tele M R 68, M L 103, A 45, T 273

The heart is very much enlarged Changes in the lungs are secondary to the cardiac condition

Electrocardiogram 2/7/33 Normal sinus rhythm T₂ inverted There is a shift of 21 degrees of the electrical axis on change of position

Course after Leaving Hospital The patient left the hospital on March 18, 1933 and was referred to the Syphilis Clinic for treatment She reported there on March 23 and received an injection of bismuth She was comfortable for only about one week after discharge when the shortness of breath returned Apparently this was inaugurated by a cold She was hoarse and had cough with mucopurulent expectoration After this the shortness of breath grew worse and edema again appeared She entered the hospital the second time on March 21, 1933

Examination Temperature, 100°, pulse, 90, respirations, 26, blood pressure, systolic 90, diastolic 62

Examination on this occasion showed essentially the same conditions reported on the first admission Dyspnea was not intense, she could lie flat without becoming short of breath There was no cyanosis The edema was somewhat more marked than on the first admission, there was pitting over the tibiae and over the sacrum The liver also was more markedly enlarged, extending to the level of the umbilicus On this occasion the pulse at times was regular, at other times there were numerous extrasystoles, and on still other occasions, for brief periods, there were paroxysms of fibrillation

Course in the Hospital (Second Admission) The patient was given digitalis She became nauseated and vomited frequently Later theocin was given This seemed also to bring on nausea Although on admission the patient's condition was far from desperate, she grew progressively worse The heart seemed gradually to enlarge, certainly it was larger than during the first admission Numerous râles were heard over the lower lobes of both lungs and signs soon developed suggesting a small pleural effusion on the right Breathing became more and more difficult

The peripheral veins were greatly engorged and the patient became cyanosed. On April 7, 1933, eight days after her second admission to the hospital, she suddenly died.

Laboratory Examinations

Blood Count 3/31/33 Hgb 62 per cent, R B C 3,200,000, W B C 15,800

Urine Specific gravity varied from 1.020 to 1.030. There was a trace of albumin.

A small number of pus cells and a few R B C in the sediment.

Electrocardiogram 4/6/33 Normal sinus rhythm P-R interval 0.22 sec

P-waves broad and notched in all leads T₁ inverted Sinus tachycardia

The temperature ranged from 99° to 101°

The pulse rate ranged from 80 to 120

The clinical diagnosis made upon the hospital ward was rheumatic heart disease, mitral stenosis and insufficiency. However, a number of observers suggested the possibility of bacterial endocarditis and when, after death, the case was finally discussed at the clinical-pathological conference, the diagnosis of bacterial endocarditis was preferred. That this diagnosis was not seriously considered during life is demonstrated by the fact that only one blood culture was taken. In addition to the clear evidence of a mitral valve lesion, anemia and a low-grade fever were conspicuous elements of the clinical features of the disease. This made it certain that the patient must have had either an active rheumatic infection or bacterial endocarditis. The rapid course of the disease was the peculiar feature which led finally to the acceptance of the diagnosis of bacterial endocarditis. From the very first onset of symptoms, on December 27, 1932, to the date of death, April 7, 1933, was a period of only a little over three months, and although improvement occurred while the patient was in the hospital, carefully treated and solicitously shielded, still, the improvement was very superficial, for only one week after leaving the hospital severe symptoms returned and shortly thereafter she died. What a contrast this is to the usual course of rheumatic heart disease. Very seldom does the rheumatic patient fail to improve satisfactorily during the first attack of heart failure and usually, long periods of relative comfort separate recurring attacks.

The postmortem examination revealed the characteristic lesions of bacterial endocarditis. The striking feature of the lesions was the advanced healing which had taken place. The valves were thickened and fibrous, in places calcified, the vegetations consisted mostly of hyaline masses and some were undergoing rapid organization. Here and there on the surface were crops of bacteria. These were gram-negative cocci, in all probability gonococci, although they did not grow in cultures and therefore could not positively be identified. There was no evidence of active or preexisting rheumatic disease. The valvular infection seemed to be a primary one, due to the gonococcus.

Brief notes from the autopsy report are as follows:

Anatomical Diagnosis Subacute bacterial endocarditis involving the mitral valve (gram-negative cocci) transplanted on intraventricular septum. Hyaline vegetations on auricular endocardium, hypertrophy of left ventricle of the heart, chronic

passive congestion of lungs and liver, infarction in spleen, thrombosis of pelvic veins, pulmonary emboli, fresh pulmonary infarcts, pulmonary edema and lobular pneumonia, myomatous uterus, chronic bilateral salpingitis, intraperitoneal adhesions

Dr. F. B. Kindell's note on the heart: The heart is enlarged, weighing 480 grams. The surface of the right auricle shows areas covered by tough little granules of organized exudate. There are punctated hemorrhages beneath the epicardium of the right ventricle. The right ventricle is a little hypertrophied. The tricuspid and pulmonary valves are thin and delicate. The left auricle is moderately dilated. There is a roughened patch in the auricular endocardium some distance above the mitral valve. Some of these thickenings are old and smoothly covered by endocardium, other little patches are made up of tiny granules which are tough and some are suggestively gritty. The mitral valve is thickened. The margins of the leaflets are gray and fibrous. The change is most marked along the edge of the aortic leaflet. There are also fresher greenish-gray vegetations along the line of closure but they are most pronounced along the chordae tendineae which are attached to one wing of the aortic leaflet. Most of these are broken. The larger masses of vegetations are distinctly tough, apparently partly organized. The marginal fringes are softer and crumbly. Three centimeters below the aortic orifice there is a granular patch suggesting partly healed vegetations on the endocardium of the interventricular septum. This is precisely in the position where the flapping loose ends of the chordae tendineae must have brushed the ventricular wall. The aortic cusps showed no lesions. The aorta, except for fine streaks of fat, has a normal intima. The larger branches of the coronary arteries are normal.

Microscopical Report: The mitral valve is quite thick and fibrous. In the small section which shows the fresher vegetations it is found that these also are of some duration. The center of the mass is calcified and it is only on the surface that crops of bacteria are found. These are gram-negative cocci, somewhat smaller than gonococci generally are. The lesion from the interventricular septum shows a thickened endocardial layer with rather numerous scattered mononuclear cells. The vegetations on the surface are hyaline. The lesions from the lining of the auricle are quite fibrous but there are hyaline masses on the surface. There are only a few minute scars in the myocardium and on the whole there is little support for the view that the older thickening of the mitral valve and the hyaline lesions in the auricle were originally rheumatic.

CASE II

J. C., 51 years, male, colored, married

A colored laborer, then 48 years of age, came to the Medical Clinic of the Out-Patient Department of the Johns Hopkins Hospital December 15, 1933, complaining of pain in the lower part of the abdomen and shortness of breath. At 19 years of age he had had an attack of rheumatic fever lasting three months. This had come on after exposure. All of the joints had been involved and were swollen and inflamed. Ten years before admission he had had an attack of sciatica in the left leg and following this he had had six or eight recurrent attacks. He said he never had had either gonorrhea or syphilis, although he described symptoms that made it almost certain that he had had a gonococcus infection at 18 years of age. In other respects he had been a healthy man, working hard until three weeks before coming to the Out-Patient Department. At that time he had had pain in the lower part of the abdomen soon followed by shortness of breath. The pain in the abdomen was described as a dull soreness. The shortness of breath progressively had gotten worse and for some nights before coming to the hospital he had been unable to lie down.

Examination: Temperature, 98°, pulse, 96, respirations, 20, blood pressure, systolic 160, diastolic 80, weight, 151 lbs.

The patient was a well-nourished colored man in no distress. The pupils reacted

actively. The teeth were in bad condition. There were no enlarged lymph nodes. The thyroid was not enlarged. The lungs were clear except for a few rales at the bases. The heart was enlarged especially to the left. At the apex there was a blowing systolic murmur transmitted to the axillary area. In the aortic area there was a harsh, rough systolic murmur transmitted into the vessels of the neck. There was a systolic thrill felt over the base. There was a blowing diastolic murmur down the left border of the sternum. There was marked peripheral pulsation and the pulse had a decided collapsing quality. The peripheral vessels were tortuous and thickened. The abdomen was somewhat distended and there was thought to be free fluid in the peritoneal cavity. The edge of the liver was felt three fingers-breadth below the costal margin. The spleen was not felt. The reflexes were all normally active.

The specific gravity of the urine was 1.024. There was a trace of sugar, no albumin. The Wassermann reaction on the blood serum was negative.

Roentgenogram. Fluoroscopic Examination. Heart enlarged, aorta diffusely dilated and rotated, no evidence of aneurysm. Some increase in the peribronchial markings. Marked infiltration at the bases probably secondary to the cardiac condition.

Film. Cardiac shadow enlarged, aorta dilated. Secondary changes in both lungs.

The patient returned to the Out-Patient Department September 4, 1936. On that occasion the Wassermann reaction was found to be positive. He then was quite short of breath and there was edema of the legs. A roentgenogram is reported. Cardiac shadow enlarged, aorta dilated, secondary changes in both lungs. Interlobar thickened pleura, right side.

The patient was admitted to the hospital September 22, 1936. There he stated that following his visit to the Out-Patient Department in December 1933 he had been quite comfortable until six weeks before this admission. Then shortness of breath on exertion had developed and gradually had increased so that he had been unable to lie down in bed and had had to spend the nights sitting in a chair. His ankles had been swollen for a month.

Examination. Temperature, 99.5°, pulse, 96, respirations, 28, blood pressure, systolic 115, diastolic 50.

The patient was described as a short, squat, pudgy-looking, middle-aged Negro. He was propped up in bed with only moderate respiratory distress. The veins in the neck were engorged. The pupils were equal and active. There were no enlarged lymph nodes. The thyroid was not enlarged. There were coarse rales at the bases of both lungs. On the right below the angle of the scapula the percussion note was a little impaired and the breath sounds were somewhat diminished in intensity. There was violent pulsation over the heart. The apex beat was a forcible thrust in the seventh interspace at the anterior axillary line. At the apex both a systolic and a diastolic murmur were heard, the latter becoming louder toward the base. The diastolic murmur was particularly loud to the left of the sternum. No thrill could be felt. The right pulse was somewhat fuller than the left. The blood pressure was the same on both sides. The abdomen was somewhat distended. The edge of the liver was felt three fingers-breadth below the costal margin. The genitalia showed no abnormality. The rectal examination was negative. The reflexes were obtained but were somewhat hypoaactive.

Course in the Hospital. On admission the temperature was somewhat elevated and during the following four days it varied between 101° and 103°, then for three days it fell almost to normal but soon rose again varying at first between 99° and 102°, later between 101° and 104°. There was a moderate degree of anemia. From time to time there were severe attacks of dyspnea. At other times he was delirious. A friction rub developed over the right lower lobe and the roentgenogram showed evi-

dence of consolidation, it is stated in the report, of the right upper lobe. Later there were dullness and fine râles over the upper portion of the left chest and a roentgenogram showed spreading consolidation on the left side. There was very little cough and almost no expectoration. Still later, signs suggesting fluid in the right pleural cavity developed. On October 10 the right pleural cavity was tapped and 30 c c of bloody fluid were removed, which contained 12,500 leukocytes per cu mm. Most of

FIG 2 Heart of Case 2 For description see text

the cells were polymorphonuclears containing gram-positive diplococci. There were also chains of diplococci, thought to be pneumococci, in the fluid. Cultures yielded a heavy growth of *Alphia streptococci*. As these signs in the lungs were developing the temperature and pulse rate rose to a higher level, the patient became more and more irrational and exhausted, and while desperately ill he died suddenly on October 10, 1933.

Laboratory Examinations

Blood Count Hgb 58 per cent, R B C 4,570,000, W B C 6,920

Later the leukocyte count rose and varied from about 10,000 to 20,000

Blood Culture No growth

Urine Specific gravity 1.023 No sugar A large amount of albumin on admission, later none Many leukocytes and a few casts in the sediment

Roentgenograms

- 9/26/36 Chest General haziness of lung field probably due to movement of patient. Area of consolidation of right upper lobe, probably lobar pneumonia
- 10/2/36 Chest There is now clouding in the left mid-lung field compatible with pneumonia
- 10/8/36 Chest Heart and aorta apparently enlarged. Diffuse clouding in right lung especially in mid-portion, probably pneumonia
- 10/9/36 Chest There is only a small amount of fluid in the right chest, the majority of the changes are due to a pneumonic process
- Electrocardiogram Fairly deep S-waves in Leads I and II. T₁ upright and small. Low take-off of S-T segment in Lead II, ending in a biphasic T-wave. T₂ inverted. Changes in Leads I and II compatible with those seen following pulmonary embolus. T-wave changes probably are due to digitalis

From these clinical data I do not see how it would be possible to make any diagnosis of the heart condition other than syphilitic aortitis with aortic insufficiency. The patient had been examined three years before the onset of his final illness and at that time showed the characteristic signs of aortic insufficiency. He had had mild symptoms of myocardial failure but no fever, no embolic phenomena and no splenic enlargement. The Wassermann reaction had been positive. Then followed a period of nearly three years without symptoms, at the end of which shortness of breath and swelling of the ankles again came on. During his second admission to the hospital the illness was dominated by the symptoms of a severe pulmonary infection which was correctly diagnosed as an infected pulmonary infarct. The symptoms of myocardial failure were inconspicuous.

Autopsy revealed the characteristic lesions of bacterial endocarditis which had almost completely healed. In stained sections the infecting organism was a gram-positive coccus, in all probability the *Streptococcus viridans*. There was no evidence whatsoever of a past or present rheumatic infection or of syphilitic aortitis. It may be that the aortic valves were congenitally bicuspid but, on account of the great deformity of the valves caused by the infection, this point could not be definitely settled.

When we consider the clinical course of events, and view the conditions found at autopsy, we cannot resist the conviction that in this patient the bacterial endocarditis eventually would have healed, had he not died untimely of the pulmonary complication.

Portions of the autopsy report are added

Anatomical Diagnosis Subacute bacterial endocarditis aortic valve, dilatation and scarring of sinuses of Valsalva (healed mycotic aneurysms, malformation?, ulceration), scarring of mitral valve, hypertrophy and dilatation left ventricle, scars, left ventricle, mural thrombi auricular appendage, emboli in pulmonary arteries, infarcts, infected gangrenous infarct, right lower lobe, infarcts in spleen, hemorrhages in kidneys, hemorrhagic pleural effusion, right, ascites, chronic passive congestion lungs and liver, small angioma of liver

Dr. W. C. MacCallum's note on the heart. The heart is quite large, the surface in general is smooth but there are pearly patches over the right ventricle and small

lenticular nodules along the coronary arteries. The coronaries are fairly straight. The left anterior descending branch shows some patches of sclerosis, these are very thin. The right is almost smooth throughout. The right auricle shows a smooth endocardium. There is a very small thrombosis in the tip of the auricular appendage. The tricuspid valve is in part quite delicate. A portion of it shows a thickening and rolling of the margin and shortening of the chordae tendineae.

The pulmonary valves are delicate. The left auricle seems hardly changed. The mitral valve is a little thickened along its line of closure and perhaps slightly contracted. The aortic leaflet of the mitral valve shows a curious translucency throughout most of its extent with a margin of more opaque white. There it is roughened a little by dark red flecks which are extremely small. There is no actual vegetation to be seen. At the beginning of the posterior leaflet there is very marked thickening which has been taken for section. This has a roughened and reddened surface and on section is about 4 mm thick, translucent and gray. It passes on into the chordae. Along the aortic segment particularly the chordae tendineae are thickened and apparently fused along the thickened margin of that valve. Along the edge of the other valve, that is the posterior segment, they are separated but there is a distinct thickening extending at least to the middle of the valve, of the margin and the line of closure.

The margin of the sinus of Valsalva at the root of the aorta is so completely altered that only a photograph or sketch can describe it. The aortic valves are practically fused together. There is only one point at which the ordinary approach of two valves to one another is seen and that is at the base of the mitral between half of the left segment and half of the posterior segment. The rest forms one thick, rigid band which is perforated by a large hole and by smaller holes, white and roughened and covered with vegetations but the sinuses are all run together as far as they lie behind this great shelf-like structure.

The orifice of the left coronary is wide, that of the right coronary is very wide but seems practically unchanged, although in the remaining space which extends deep down below these coronary orifices, there are great depressions lined by pearly scar-like material, in places covered by fresh vegetations, in places extending so as to isolate cord-like strands from the aorta down to the sinus.

Just above the level of the sinus of Valsalva the aorta becomes perfectly normal and smooth. This, however, extends only to about the middle of the arch. Below the aortic valve the septum membranaceum is thickened by gray or pearly bands. The back of the mitral valve is rigid, yellowish and roughened. Toward the aortic valve it is much more roughened, evidently from the implantation of a vegetation. The myocardium is not much affected.

The aorta past the margin of the large vessels shows some sclerotic change. Below that in the thoracic aorta the wall is fairly elastic. It is flecked with tiny patches of whitish opacity and there is a delicate striation along the whole course. These flecks become a little more emphasized below the renals and there are some yellow patches.

The left lung is smooth externally throughout the upper lobe. In the lower lobe there are two projecting patches which are somewhat reddened. On section the upper lobe seems air-containing except for a small patch which is fairly firm in the lower part. In the middle of the lower lobe there is a quite distinct infarct.

The right lung shows a fibrous, somewhat hemorrhagic exudate on the surface. The upper lobe shows a patch of consolidation in its lower margin which on section is somewhat hemorrhagic and shows a thrombus in the central blood vessels. It is quite sharply outlined. It has in general the appearance of an infarct. In the middle lobe the brown pigmentation of the lung is particularly striking but it seems to be air-containing throughout.

In the lower lobe there is a large area of consolidation which is deep red and has

in general something of the appearance of an infarct but the central part is hollowed out into ragged cavities with greenish, discolored walls which communicate with one another. The large vessel passing to this area is plugged by a thrombus.

Microscopical notes. Cultures from the valves showed many different organisms. In smears the predominant organism was a gram-positive coccus occurring in threads and in long and short chains.

CASE III

W. S., 50 years, male, colored, single.

A colored laborer, 50 years of age, entered the Johns Hopkins Hospital, January 24, 1934, complaining of shortness of breath. He had been in the hospital previously from January 16 to January 19, 1922. The diagnosis was syphilis, aortic insufficiency, chronic alcoholism. Following his discharge in January 1922, the patient

144 J. W.

FIG. 3. Heart of Case 4. For description see text.

apparently had gotten along well and had worked hard. When admitted to the hospital January 24, 1934, he said he had been somewhat short of breath for a great many years but this had caused him no great inconvenience until December 1933 when he had become progressively more and more short of breath and the ankles and legs had become swollen. At the end of December he had had some fever and from then on his shortness of breath had become very severe. He had been unable to lie flat in bed, indeed, had spent most of the time sitting in a chair.

Examination. Temperature, 99.6°, pulse, 100, respirations, 26, blood pressure, systolic 190, diastolic 60.

The patient was in great respiratory distress, it was difficult for him to talk on account of the shortness of breath, his respirations were rapid and labored. He had an anxious expression. He had a rasping cough and occasionally brought up a little mucoid sputum. Breathing was Cheyne-Stokes in character. There was marked edema of the legs and over the lower part of the back. He was very cyanotic. The eyes were normally prominent, pupils equal, regular, reacted actively to light and on accommodation. Extra-ocular movements were well performed. The retinal arteries were somewhat narrow and tortuous, and the veins rather full. The teeth were in very poor condition. The pharynx was somewhat injected. No enlarged superficial lymph nodes. Thyroid not enlarged. The chest was full and rounded, symmetrical. The lungs were clear except for numerous moist râles over the lower lobes. The heart seemed to be greatly enlarged. No localized apex beat could be made out. The area of cardiac dullness measured 4 cm to the right and 12 cm to the left of the midline. There was a band of dullness over the manubrium measuring 7 cm. The heart's action was very rapid but regular. At the apex a definite thrill could be felt, its time in the cardiac cycle could not be determined. The first sound at the apex was very loud and was preceded by a rumbling murmur, late in diastole, it was accompanied and followed by a soft, blowing systolic murmur. Over the body of the heart there was a proto-diastolic gallop. In the aortic area the sounds were heard with difficulty. There was a distant, rough systolic murmur, the second aortic sound was not clearly distinguished and seemed to be replaced by a diastolic murmur which was heard also to the left of the sternum. The second pulmonary sound was accentuated. The pulse was regular, moderately collapsing in quality, a capillary pulse was visible in the nails. There was moderate thickening of the peripheral vessels and considerable throbbing. The abdomen was prominent, there was a moderate degree of ascites. The liver was enlarged, extending a hands-breadth below the costal margin. The spleen was not felt. Genitalia showed nothing abnormal. The reflexes were normally active.

Course in the Hospital The patient made a prompt and remarkable recovery. After three or four days he was comfortable and at the end of five days was able to lie flat in bed. As the heart rate slowed the sounds could be more carefully observed. The apex beat now could be felt in the sixth interspace almost as far out as the anterior axillary line. All observers agreed that the first sound at the apex was loud and that there was a definite rumbling murmur late in diastole. There also was a systolic murmur and an early diastolic murmur. At times the diastolic murmur at the base was not very pronounced and some observers even doubted the existence of aortic insufficiency. However, in the end everyone agreed to the presence of aortic insufficiency and most observers were of the opinion that there was definite evidence of mitral disease as well. There seems to have been a remarkable reduction in the size of the heart as the patient improved, for a roentgenogram taken shortly before his discharge shows the heart to be but little enlarged. As the patient improved a very loud systolic murmur was heard in the tricuspid area. The blood pressure on admission was elevated, on one occasion as high as systolic 200, diastolic 90. As he improved the blood pressure gradually fell and when he was discharged from the hospital the reading was systolic 142, diastolic 58. On one occasion it had been as low as systolic 112, diastolic 56. He was discharged in good condition on February 27, 1934.

Laboratory Examinations

| Blood Count | Hgb | R B C | W B C |
|--|--------------|-----------|--------|
| On admission | 74 per cent | 3,700,000 | 12,750 |
| On discharge | 110 per cent | | 7,840 |
| Wassermann reaction on the blood serum | Negative | | |
| Blood Culture | No growth | | |

Urine Specific gravity 1.016 to 1.022 A trace of albumin No sugar A moderate number of leukocytes and a small number of casts in the sediment
Temperature on admission varied from 98° to 100° On discharge it was oscillating between 98.6° and 99.6°

Electrocardiogram Normal sinus rhythm Levogram Slight slurring of QRS complexes in all leads T-waves inverted in I and II, iso-electric in Lead III

Roentgenogram

Chest Cardiac shadow slightly enlarged Tuberculous, fibroid infiltration left upper and middle portion of lung

Tele M R 47, M L 98, A 62, T 28

After discharge from the hospital on February 27, 1934, the patient made a number of visits to the Out-Patient Department and then returned no more On October 22, 1936, he was admitted to the City Hospital desperately ill and died later on the same day He stated that during the two previous months he had suffered from ever increasing shortness of breath, swelling of the legs, and cough with frothy, blood-tinged sputum Only a hurried physical examination could be made, the notes of which record moderate enlargement of the heart, the signs of mitral stenosis and insufficiency, and the usual evidence of chronic passive congestion The signs of aortic insufficiency were overlooked or misinterpreted

Considering the clinical evidence presented by this patient one is forced to make the diagnosis of rheumatic heart disease He was first observed in 1922 at which time he had a characteristic aortic insufficiency without symptoms He remained well until 1933 when the first symptoms of myocardial failure came on Again, examination revealed the signs of aortic insufficiency and in addition the signs of a mitral lesion He died of heart failure in 1936, fourteen years after the valve lesion had first been discovered

I shall not dwell upon the erroneous diagnosis of mitral stenosis, for it is only too well known how difficult it is to decide upon the condition of the mitral valves in the presence of aortic insufficiency I wish merely to remark that the clinical assumption that in addition to aortic insufficiency the patient did have mitral stenosis, made the diagnosis of rheumatic heart disease seem doubly secure

As a perusal of the autopsy notes will show there was no disease of the mitral valves Only the aortic valves were affected and these in a manner which leaves little doubt that the original infection was bacterial and not rheumatic We must realize that it is never possible from the inspection of old healed scars to state with complete assurance the precise nature of the injury which caused them However, in this instance the appearance of the valves is so characteristic that a positive statement is justified even though not entirely certain

Anatomical Diagnosis Scarring, calcification, insufficiency and stenosis of the aortic valve (healed bacterial endocarditis?), calcified plaques above commissures of the aortic valve, history of treated syphilis, history of hypertension, cardiac hypertrophy and dilatation, scars in the myocardium and epicardium, chronic passive congestion, anasarca, calcified tubercle at apex of left lung and in left bronchial lymph node, slight emphysema and anthracosis, (long standing history of mitral stenosis)

Dr S S Blackman's note on the heart The heart is quite large The chambers are all dilated and hypertrophied but the hypertrophy is chiefly on the left side There are a few tendinous patches on the epicardial surface The tricuspid valve is practically normal At one point, there is slight thickening along the line of closure of one anterior leaf The left auricle shows no evidence of an old rheumatic patch The mitral valve is practically delicate and looks anatomically competent At the junction of the anterior and posterior cusps, there is a slight thickening along the line of closure in a small localized area The endocardium above is very finely granular The chordae tendineae are not scarred or shortened There are only a few small yellow patches in the aortic leaf of the mitral valve The aortic cusps are all very much thickened and deformed The thickening and calcification which are marked are most marked along the line of closure and the changes further down where the valves fuse with the endocardium of the septum are much less marked The commissures are all greatly thickened and not calcified There are calcified nodules projecting toward the ventricle and into the sinuses of Valsalva There is a good-sized, circumscribed plaque in the aorta at the point of insertion of each cusp These plaques are now calcified The largest one is above the point of insertion of the right and left cusps and this plaque is about 2 cm in diameter The adjacent margins of the right and left aortic cusps below this plaque are fused together to form a calcified mass which is nearly 1 cm wide It bulges out towards the ventricle for nearly an equal distance and where the separation finally does take place, there is a wide gap between the two in which there is a little coagulated blood and some yellowish granular material suggesting fibrin All of the altered commissures are pulled down and somewhat retracted and the valve is evidently insufficient and somewhat stenosed too The mouths of the coronaries are not narrowed and there is very little coronary sclerosis However, one can see definite gray scars in the myocardium near the base In the posterior papillary muscle there are numerous evident gray scars There is not enough evident sclerosis of the coronary arteries to account for these scars However, the mouth of the right coronary lies between the two plaques already described, and these do extend in the aorta as far as the very edge of the coronary mouth Although it is not narrowed, the elasticity of the aorta on either side of it is evidently lost The ascending aorta besides the plaques mentioned is perfectly delicate and smooth for in the rest of the aorta too, there is very little sclerosis There are a few calcified plaques in the arch and in the lower part a few yellow streaks and one or two little calcified plaques but no definite syphilitic lesions and really very little arteriosclerosis

The other organs show chronic passive congestion

CASE IV

G D, 65 years, female, white, divorced

A white woman, 65 years of age, entered the Johns Hopkins Hospital October 12, 1935, complaining of shortness of breath and swelling of the legs She always had been a hard-working woman and was well until four years before admission when she began to have attacks of indigestion The symptoms became so severe that she entered a hospital at Philadelphia where they treated her by washing out the kidneys After leaving the hospital she began to notice shortness of breath on exertion and occasionally the ankles were somewhat swollen The shortness of breath gradually increased and at the end of 1933 she was so troubled with dyspnea and swelling of the legs that she had to give up her work and go to live with a relative Even though she now lived very quietly she did not improve Her shortness of breath finally became so severe that she entered a hospital at Lebanon, Pa When she left the hospital at the end of five weeks she was much better

One year before her admission she had an upper respiratory infection and all

of her old symptoms returned. She was quite short of breath and her legs were swollen. From then on she was always short of breath and the ankles were swollen from time to time. Five weeks before entering the hospital the abdomen began to swell and her shortness of breath became more and more severe. Three days before admission she had nausea and severe vomiting. She came to Baltimore and was admitted to the hospital through the Accident Room.

Examination Temperature, 98.4°, pulse, 145, respirations, 28, blood pressure, systolic 166, diastolic 110.

The patient was a well-developed, well-nourished woman propped up in bed with a moderate degree of respiratory distress. She was very deaf which made it difficult to get a detailed history. There was a little cyanosis of the lips and nails. There was extensive edema of the legs, ankles, thighs, over the sacrum and back and a little over the arms and wrists. The eyes were normally prominent, pupils were equal, reacted actively. There was a slight arcus senilis. The retinal veins were somewhat engorged, the arteries somewhat narrowed and tortuous though not conspicuously so. There was slight compression of the veins where the arteries passed over them. A few small recent hemorrhages were seen. All the teeth had been extracted. The pharynx showed nothing remarkable. There was no enlargement of the superficial lymph nodes. Thyroid was not enlarged. The chest was well formed, it moved somewhat as a whole. The lungs were clear except for a few moist râles over the lower front on both sides and in back below the angle of the scapula. The apex beat of the heart was in the fifth interspace 9 cm. to the left of the midline. Area of cardiac dullness measured 5 cm. to the right and 11½ cm. to the left of the midline. The heart's rhythm was totally irregular. The first sound at the apex was followed by a very loud, blowing systolic murmur. At the base the second pulmonary sound seemed to be louder than the second aortic. The peripheral vessels were tortuous and thickened. The pulse was equal at the two wrists, totally irregular. The abdomen was greatly distended. There was evidence of considerable accumulation of ascitic fluid. The edge of the liver was felt 9 cm. below the costal margin. The spleen was not felt. The neurological examination was negative.

Course in the Hospital The patient was twice bled and given digitalis but there was little if any improvement in her symptoms. Later a profuse diuresis occurred after which the edema lessened, the dyspnea was less oppressive and the patient became more comfortable. However, this improvement lasted but a short while, soon she was just as much swollen as before, her breathing was difficult and she became quite drowsy following the liberal administration of ammonium chloride. On October 27 she began to vomit, she rapidly grew worse and died later that day.

Laboratory Examinations

Blood Count Hgb 115 per cent, R B C 5,040,000, W B C 10,000

Wassermann reaction on the blood serum was strongly positive

Blood chemical studies

| | NPN | CO ₂ | Plasma Prot |
|------------|----------------|-----------------|-------------|
| October 12 | 34 mg per cent | | |
| October 18 | 34 mg per cent | 56 | 6.8 gm |
| October 21 | 60 mg per cent | | 6.5 gm |
| October 24 | | 27.7 | |

Spinal Puncture Colorless fluid 2 cells Negative Pandy Negative Wassermann reaction

Urine Specific gravity 1.009 to 1.020 No sugar, albumin—a trace A small number of leukocytes and an occasional cast in the sediment

The temperature varied from 96° to 100°

The pulse rate varied from 80 to 140

Electrocardiograms

October 18, 1935 The dominant rhythm is nodal There are extrasystoles occurring at every second beat giving rise to a typical bigeminal rhythm There are occasional paroxysms of extrasystoles arising from a different ectopic focus giving rise to runs of paroxysmal ventricular tachycardia at a rate of 125

October 27, 1935 Auriculo-ventricular nodal rhythm Dextrogram Nodal tachycardia

Here we have a characteristic instance of mitral stenosis in a woman 65 years of age, the symptoms first appearing late in life Under these circumstances we are seldom wrong in concluding that the lesion is the result of a former rheumatic infection However, in this instance the scarred appearance of the valves as seen at the postmortem examination resembles much more closely the results of a bacterial than of a rheumatic infection I do not pretend that the distinction can be made with confidence although I think the evidence makes the conclusion highly probable

Anatomical Diagnosis Mitral stenosis and calcification Cardiac hypertrophy Chronic passive congestion of viscera Syphilis (Wassermann) Arteriosclerosis Localized atrophy of kidney from arterial sclerosis Hemorrhages in urinary bladder

Dr S Jarcho's note on the heart The heart which weighs 550 gm is distinctly larger than normal There is perceptible dilatation of the right auricle The tricuspid valve presents a moderate degree of fibrous thickening along the line of closure especially marked on the anterior leaflets The chordae tendineae are opaque but not appreciably shortened There is distinct hypertrophy of the right ventricle No changes are found in the pulmonary cusps The left auricle is markedly dilated and moderately hypertrophied The endocardium is thickened but no discrete auricular patch is seen The mitral orifice is much narrower than normal and is fixed by the calcification of part of the valve When the valve is opened its edge is seen to have formed a thickened shelf with rounded edge, irregular, rough calcified masses are found at intervals along the valve The chordae tendineae are greatly shortened They are opaque and end without ramifying The endocardium over the apices of the papillaris muscles is distinctly opaque and the papillaris muscles themselves are much broader and thicker than normal There is distinct eccentric hypertrophy of the left ventricle The aortic cusps are very little thicker than normal but are fused for approximately 4 mm along the respective commissures The corpora arantii are not altered No verrucae are seen The myocardium is somewhat flabby and contains a very few inconspicuous scars

Microscopical Notes Section through the left ventricle, left auricle and mitral valve shows thickening and fibrosis of the valve and of its base with no signs of active inflammation The auricle is thickened in the endocardium and myocardium The latter shows mononuclear infiltration but not characteristic of Aschoff bodies Similar infiltrations are encountered in the epicardium which in addition is slightly scarred The ventricular myocardium shows a few perivascular scars and one vascular collection of round cells

Additional section shows dense hyaline thickening of the mitral valve and a small area of calcification The myocardium presents scattered tiny mononuclear infiltrations which are not numerous and not regularly perivascular The coronary vessels show very slight intimal thickening

Other sections taken through the anterior papillaris muscle, left ventricular and auricular ring, the intraventricular septum and right ventricle and pulmonary valve show a few tiny myocardial scars There is no evidence of active inflammation

THE PSYCHO-BIOLOGY OF BREATHING¹

By CARL BINGER, M D , *New York, N Y*

THIS paper deals with what I have called the psycho-biology of breathing and its relation to diseases of the respiratory system. In it I have attempted to review the essential physiological facts of respiration and to indicate, when possible, links between our physiological and psychological knowledge. The connections will not always be obvious, but it seems a sound method of procedure to begin with known facts in each field and to try to bring them into relation with each other.

It may be objected by some that the laws of the body do not govern the laws of the mind—that the chasm which separates these two hemispheres cannot be bridged and certainly not by arguments based on analogy. I suspect that the split exists partially within us—is part of our own subjective ambivalence which we project on to the material under investigation and that even such divergent technics of inquiry as physiology and psychoanalysis are not so remote from one another as certain purely fortuitous circumstances have made them appear to be.

The method of psychoanalysis has contributed much to our understanding of neurotic disorders. It has provided us also with an entering wedge into some of the more obscure etiological problems of so-called functional and organic disease. But no one will deny that our knowledge is still in the form of first and rough approximation. We must try, as Santyana used to say "to define the limits of our ignorance." Nor need there be any quarrels between so-called organicist and functionalist—if that is the proper title to give his adversary. No one has a sole proprietary right to explore the secrets of nature, and each man must select the method of study that is congenial to him.

Let me now proceed to more practical matters.

A young European girl of aristocratic origin and background made up her mind against her parents' will to go to a university. She had always been a somewhat shy, reticent, easily depressed child readily inclined to tears, and rather solitary. There were many difficulties at home. The parents were not happily married. There was much friction in the atmosphere and little love, although her mother was constantly concerned with the daughter's welfare. The girl had outspoken artistic interests. She loved music, the theatre and had a respectable talent for drawing. She was on the other hand greatly interested in languages—waverling indeed between the two interests. This was a source of conflict not only in her but between her parents and herself. Finally she decided to pursue the study of languages and only after much persuasion and against great resistance could she win her parents' unwilling consent. They were by no means liberal with her in financial matters so that at the university she lived

* Received for publication May 6, 1937

in modest isolation. In the course of the second semester she began to realize that academic work was not giving her the release and satisfaction she had hoped for. Naturally this made her very unhappy but she tried with all her might to push through her plan to study, if only not to be upbraided by her father. She dragged along until the close of the semester hardly able to follow the lectures properly.

During the holidays she returned home only to hear reproaches because she looked so badly and because of her moods. She was sent to a doctor who found nothing. Constantly she was assailed by doubts as to the wisdom of further pursuing her studies. After a most unpleasant scene with her parents she became depressed and then began to cough. This again took her to the doctor who could find nothing. But the cough persisted. Upon returning to the university she consulted a specialist who at first found, as we say, nothing in her chest, but repeated examinations and roentgen-ray studies disclosed an incipient process at the right apex.

The second case I wish to describe concerns a man in his early thirties, always in excellent health, in good financial circumstances and happily married to a young woman also apparently in perfect health. During her untroubled pregnancy the husband pursued his usual business activities, was much engaged in sports, indeed even rode in steeple-chases. The wife's delivery was difficult and shortly thereafter she began to fail from what was subsequently proved to be a hydatid mole. Her illness lasted about a year when she died. The husband had not given up hope of recovery until a few weeks before the end, and in spite of his intense worry he continued in good health. As soon as the hopelessness of her condition became clear to him he began to feel badly, became depressed and quite lost his joy of living. After his wife's death his depression grew worse. Within a few weeks he had a slight pulmonary hemorrhage which he himself did not relate to a disease of the lungs, as such a possibility had not occurred to him. Upon examination, however, the diagnosis of phthisis was established.

These two abstracts of case histories are taken from a book by E. Stern¹ called "*Die Psyche des Lungenkranken*" which discusses wisely and sympathetically such problems as the reaction of patients to a diagnosis of pulmonary tuberculosis and to sanatorium life, the relationship of doctor and patient in chronic illnesses, the psychic factors in the etiology of tuberculosis. He includes a series of skillful vignettes of patients' lives in which are described, as in the ones which I have reported, long periods of tension, ambivalence and frustration which lead gradually to fatigue states, hopelessness and depression and in which the denouement is the discovery of an apical process, with a temporary resolution of the conflict by sanatorium treatment.

An extensive literature has sprung up in this field. Within the past five years the Quarterly Cumulative Index has published a new subheading "*Mental Aspects*" under Tuberculosis. Naturally we do not know what mechanisms are involved here—nor how states of tension and conflict prepare the body for the invasion of the tubercle as they appear to do. It is of importance in the first instance to establish the fact of such relationships before essaying the far more complex problem of explaining them. This first step then is a practical point of departure—a more complete and psychiatric, if you will, anamnesis of patients suffering from incipient pulmonary tuberculosis.

What we observe in these life histories is a coincidence of events. Per

haps it would help us if we dismissed from our minds, for the moment thoughts of causality, clichés about psychogenic and somatic disease or functional versus organic and looked upon these examples and upon others, which I will present as simultaneous physical and mental phenomena. From a metaphysical point of view as well as from that of modern physics the question has been raised as to whether the discussion concerning cause and effect about which we talk with so much assurance and dogmatism has in it any inherent logic other than one of temporal and statistical relationship. And so I should like to stress as our point of departure the idea of *coincidence* the coincidental happenings in the realm of the mind and of the body in relation to certain specific inner trends and outer situations. This mode of orientation toward our patients is important as it will affect our clinical judgment both in diagnosis and treatment.

I have dealt here with pulmonary tuberculosis first because it represents one of the most important of the diseases of the respiratory apparatus, secondly because problems of pulmonary ventilation may have an etiological bearing on the location of the lesion. If psychological determinants play a part in the occurrence of this disease it is reasonable to shift our ground for the moment and to look upon the phenomenon of pulmonary ventilation from this point of view as well. Speaking teleologically breathing is designed to supply the tissues with oxygen. This function is so vital to survival of the organism that we may expect to find that forces voluntary and involuntary, reflex chemical, homeostatic as well as affective, combine to insure its perfect performance.

Breathing is in more than one sense a twofold function. It is usually thought of as consisting of an external and internal process. External respiration has to do with bringing the organism into gaseous equilibrium with its outer atmospheric environment. Internal respiration is concerned with the transport of gases in the blood stream and their diffusion to the tissue cells. The exchange of gases takes place at the surface of the respiratory epithelium whether the air properly warmed and moistened has been brought after its passage through the upper respiratory tract. Here we see a rough analogy to the preparation of food in the mouth before it passes down the gullet into the stomach. I shall refer again to this analogy.

Breathing is normally adjusted to maintain a fairly constant composition of the alveolar air, because the alveolar air regulates the tension of gases in the arterial blood. Enough fresh air has to be introduced into the alveoli to replace the oxygen taken up by the blood, and to get rid of the CO_2 which has come out of the blood. The venous blood which comes to the lungs gives off CO_2 and takes up oxygen until it comes into equilibrium with the air in the alveoli. The tension of gases in the arterial blood is therefore normally about the same as in alveolar air. As we shall see later this reciprocally related process of oxygen absorption and CO_2 elimination not only insures adequate ventilation of the blood and tissues but also affects

the function of the respiratory center which is extraordinarily sensitive to changes in tension of gases in the blood

Embryologically the pulmonary respiratory apparatus develops from the hind part of the ventral wall of the head gut. Immediately behind the thyroid gland a median groove, the rudiment of the trachea, is detached from the gullet. From its hinder end a couple of vesicles develop—the simple tubular rudiments of the right and left lungs. As the respiratory apparatus is genetically and structurally related to the gastrointestinal tract, so its function seems to present an analogue of the latter. I do not mean to imply that the analogy of function derives from their common site of origin though this is an interesting field for speculation. However, both systems are concerned with the incorporation of certain substances of the external environment, with the transport of these substances to the tissue cells and with the excretion of certain products of tissue metabolism. Both digestive and respiratory systems seem susceptible to similar derangements, for example to spasms, to forced expulsion, to changes in secretion and both may become pathways for the entrance of infectious organisms. If Alexander² is correct in his assumption that the gastrointestinal tract may act out certain emotional trends having to do with ingestion, retention and elimination it is conceivable that an organ system presenting aspects so closely parallel embryologically and functionally to it can exhibit similar responses for embodying similar trends. It remains, however, for future scientific inquiry to explore the problem of psychological engrams as it has undertaken to do with physiological ones.

We have just seen that the respiratory apparatus in its rudimentary embryological form consists of a system of simple tubes. From the phylogenetic point of view this same fact holds. In the lower forms, as for example the insectivora, there are no lungs but tracheae through which atmospheric oxygen passes by simple diffusion. It is believed that respiratory movements begin at that point in the phylogenetic scale where the size of the organism and the length of its tracheae no longer permit adequate ventilation at the existing partial pressure of atmospheric oxygen. An interesting parallel to this concept can be observed in man, whose respiratory movements may disappear when he is placed in an artificial environment in which atmospheric pressure is caused to fluctuate rhythmically above and below normal pressure. Again we are confronted by an analogy with the gastrointestinal system. The fetus is nourished passively by diffusion and osmosis through the chorionic villi—only later after birth to use actively its sucking and swallowing mechanism for the ingestion of food. From a phylogenetic point of view we see in the lower forms, such as protozoa, nourishment occurring by osmosis and diffusion and only much later the differentiation of gastrointestinal tracts and the establishment of mouth parts equipped for sucking, biting, chewing and swallowing.

In the field of psycho-pathology we are familiar enough with patients

who refuse to eat even to the point of starving themselves to death. Similar reactions to breathing are not so common but are by no means unheard of. One needs to think only of the stubborn angry child who holds his breath in a temper tantum to the point of cyanosis, of the Sudanese negro who can die of asphyxia by holding his breath, and of the common and ancient form of suicide by strangulation or hanging, which like other forms of suicide is thought to express certain unconscious determinants.

As there is an analogy in the structure and function and in what might be called the psycho-pathological equivalents of these two systems so also are there certain linguistic forms the use of which suggests parallel origins. I shall mention only the fact that deep labored breathing of diabetic coma and acidosis is sometimes described as "air hunger." Many individuals during periods of tension or excitement actually swallow air.

Psychoanalysts are familiar enough with these substitutions of one organ system for another and of what appears to be—perhaps because of our lack of understanding—the welter and confusion of unconscious thought. The breath, for example, may take on the meaning of food and both may be related to fantasies of impregnation. Words may be feces, the voice the phallus. Bizarre as these interpretations may sound they are in fact not interpretations but what our patients often tell us if we are willing and able to listen to them.

Continuing with the theme of organ displacement we are familiar with vasomotor changes such as blushing and the engorgement of the erectile tissue of the nasal turbinates, which are related to emotional disturbances, also with so-called vicarious menstruation and with the treatment of dysmenorrhea by applications to the nasal mucous membrane. Whether this therapeutic procedure is founded in fact or fantasy I do not know. Frequently we encounter the so-called hysterical globus phenomenon which appears also to be a displacement and often to be related to fantasies of oral impregnation. I had recently the opportunity to observe one in *statu nascendi* and since the respiratory system was at least subjectively involved I shall describe it.

A woman of 25, married but childless, who is suffering from a severe mixed neurosis in which anxiety states and obsessional ideas predominate, was recounting a nightmare to me. She could not recall its content—only the fact that she felt an enormous weight on her chest and that she was unable to get her breath or utter a sound. This is a familiar enough setting for nocturnal terror. While she was talking the feeling returned. She lay quite motionless and said that she felt a great weight pressing on her chest as if she were unable to breathe. She then said "Aren't there stories about cats lying on babies' chests and sucking their breath away?" This patient was brought up in intimate association with a pet cat who in many respects was a rival preferred by her mother. She is the only patient whom I have seen to whom an animal has played the rôle of sibling and who has in many respects identified herself with a cat. She constantly dreams of a mother cat and kittens, of kittens being born in the toilet and of poor, starved, thin, homeless kittens. When she passes a stray cat on the street she is overcome with a desire to take it

home and mother it. The next step in the story is she now felt the weight lying on her chest was a cat. This was in no sense an hallucination. It was a fantasy. She continued to feel breathless and then told me she felt the cat was inside her chest. After awhile the feeling of substernal oppression passed and the patient then complained of a lump in her throat which made her feel as if she were strangling. This in turn passed off and she again breathed quietly and easily. A few days before this experience she told me of a dream in which some birds fell over as if dead, whereupon little birds appeared to hop out through the bigger birds' chest walls. She has a constant fear of death as she has of sexuality and childbirth which are closely associated in her mind with the idea of dying. Paradoxically enough she has a strong suicidal drive, as if indeed she wanted to jump into the lake to escape the rain.

The feeling of being unable to take a deep breath, i.e. dyspnea, is commonly encountered in anxiety states, indeed the sensation itself undoubtedly gives rise in some individuals, though not in all, to feelings of anxiety. Dyspnea is properly speaking a subjective symptom, not an outward sign. It has been defined by Means³ as "the *consciousness of the necessity for increased respiratory effort*". It will occur, as Means says, whenever the respiratory mechanism cannot with ease function to the extent that bodily processes require. It is an interesting fact that consciousness is directed to the thorax or diaphragmatic region while the cause of the difficulty may be either in the lungs or in some far distant part of the body. The most common cause of dyspnea is physical exertion.⁴ The increased pulmonary ventilation is then the result of increased metabolism. This does not lead to any distressing symptoms until the demand for oxygen and elimination of carbon dioxide is greater than the lungs can perform with comfort. Thyrotoxicosis and febrile states may produce a similar type of dyspnea due to excessive metabolic demands. A different mechanism, yet one occasioning the same subjective sensation, may result from anemia, anoxemia, changes in the acid-base equilibrium of the blood and tissues, or decrease in cardiac output. In each one of these the disability and distress are referred to the breathing apparatus—just as it is in those conditions such as pneumonia, congestive heart failure, pulmonary fibrosis, emphysema, and bronchial asthma where the fault actually lies in decreased efficiency of the pulmonary bellows and is associated with reduction in vital capacity and pulmonary elasticity. The localization of respiratory distress in the region of the diaphragm even when the pathological lesion is remote is an interesting phenomenon. It seems almost like a conditioning or like a projection, as if the patient were saying "I can't breathe easily, therefore there must be something wrong in my chest". Perhaps, however, the sensation is experienced where it is because existing nervous pathways can convey it nowhere else. It is apparently a well canalized one, for many sensations of excitement and anxiety are felt in the same zone. Those of us who were in the war saw numerous cases of so-called *neuromuscular asthemia* or *disordered action of the heart* in which shortness of breath played a prominent part. I remember an enormous black negro in a white night shirt sitting up in bed and breathing at the rate of 120 per minute with nothing abnormal disclosed.

on the physical examination to account for such a disturbance. In some of the more severe cases of this sort pronounced cyanosis appeared and even collapse from what was thought to be exhaustion of the respiratory center. Very often, however, during sleep or hypnosis the respiratory rate returned to normal. That the condition was associated with an acute anxiety state with suppression of affect is not improbable. The physiological explanation given for this type of rapid and shallow breathing is that "the normal reflexes are preternaturally hypersensitive". Breathing is, to be sure, only partially controlled by reflex mechanisms. In the control and regulation of the rate and depth of breathing its twofold character is again in evidence. Its regulation is partly nervous, partly chemical. It is partly reflex, partly under voluntary control. In this respect it differs somewhat from the other two great vegetative systems, the cardiovascular and the gastrointestinal, and resembles more nearly the mechanism of the sexual function. It is perhaps because it represents a meeting point of conscious and automatic activity that it so easily lends itself to an expression of emotional tensions and disturbances.

The impulse to breathe arises in the so-called respiratory center which is located somewhere in the medulla oblongata about at the level of the *striae acousticae*. This locus was first identified in 1811 by Le Gallois.⁶ The center apparently discharges at a constant slow rate sending impulses to the intercostal muscles along motor fibers of the spinal nerves and to the diaphragm through the phrenic nerves. Recently these rhythmically discharging impulses have been studied and graphically recorded in the cat by Adrian.⁷ Their origin is of course unknown but they appear to resemble the so-called Berger waves from the cerebral cortex. The activity of the center is exquisitely sensitive to changes in the H-ion concentration of the blood and the lymph which bathes it and perhaps specifically to CO₂ and also, of course, to oxygen want. Since oxygen want constitutes a profound threat to the integrity of the organism, more especially to the functioning of cortical and autonomic centers, it is probable that the feeling of anxiety and panic induced by asphyxial states serves as a danger signal to the individual. We are familiar with Freud's concept of anxiety as a danger signal. Whether anxiety, more specifically neurotic anxiety, is related to anoxemia as Deutsch⁸ has intimated, we do not know. This is a problem which could be investigated. McFarland and Barach⁹ have recently exposed a group of psycho-neurotic individuals to low partial pressures of oxygen. They found that these patients tolerated low atmospheric oxygen less well than a control group. There is in all probability a high degree of individual variation in this. Some individuals respond to anoxemia and shortness of breath with feelings of anxiety and others do not, perhaps depending upon their capacities to function physiologically at low oxygen tension, and perhaps also upon their earlier conditioning in respect to these states. I shall not deal here with work which has been done on the effects of low oxygen tensions on sensory

reaction times, muscular coordination, discriminative judgments, etc. I refer to observations made with rebreathing apparatus and low pressure chambers especially in relation to testing of fliers, also to observations made at high altitudes. The recent International High Altitude Expedition to the Andes¹⁰ has furnished some data which may make it possible to predict which individuals will tolerate low oxygen pressures well and which will not. This, to be sure, is a different problem from the one to which I have already referred, i.e. the relation of anxiety to anoxic states.

Chemical stimuli determine to what extent inflation and deflation will occur but probably have little influence upon the frequency of respirations. The latter is governed by a sensory reflex mechanism first described in 1868 by Hering and Breuer¹¹. Afferent sensory impulses from the lungs reach the center by way of the vagus nerves. Their existence has been demonstrated not only by cutting and freezing experiments which elicit typical slow, deep, so-called vagal, breathing, but action currents of afferent vagal impulses synchronous with respiration were demonstrated by Einthoven¹². The vagi, as the great afferent nerves of the lungs, serve in the complicated apparatus to protect them against the effects of excessive distention or collapse. They inform the respiratory center of movements of air currents and the position of the lungs, and reflexly check the depth of breathing. The chemical factors therefore control the total pulmonary ventilation, the afferent vagal impulses control the rhythm of breathing. I have not dealt here with the less understood function of intrinsic sympathetic pulmonary and bronchial ganglionic plexuses. In general, as Means¹³ says, the nervous control of breathing may be expected to secure for us that respiratory type which in accordance with the local condition in our chest or abdomen, may most comfortably supply the ventilation required for the gas exchange which our general bodily processes may happen at any time to demand.

I have described this subject of the control of the depth and rate of breathing for two reasons. First, because a recent attempt has been made by Alexander and Saul¹⁴ to relate the form of the respiratory curve to certain personality traits, second, because a discussion of the nervous control of respiration leads naturally to a consideration of asthma in which occurs a reflex stimulation of the smooth muscle of the bronchial wall through vagal broncho-constrictor fibers and in which an emotional element plays a rôle of major importance.

Regarding Alexander and Saul's work, I have, to be sure, seen only an abstract. They believe they have shown that a certain correlation exists between the form of the respiratory curve and certain libidinal trends. That the respiratory curve is influenced by anxiety, by tension and even by a specific personality factor, I am quite ready to believe. But to establish the fact that a correlation exists between the form of the respiratory tracing and specific instinctual drives would require a large statistical material. Alexander and Saul are quite aware of this. They present their conclusions with

appropriate caution and modesty I am glad to learn that Deutsch and Finesinger¹⁵ are also engaged in investigating this problem with particular attention to the influence of induced affective states on the form of the respiratory curve

Turning now to the subject of asthma I should like to summarize certain findings concerning it in the psycho-somatic field That asthmatic attacks are often closely bound to certain specific life situations is now common knowledge Psychotherapy, after other methods of treatment have failed, has in some individuals brought about the disappearance of Charcot-Leyden crystals, Curschmann's spirals and even of eosinophilia from the sputum and blood I refer to a series of cases reported upon by Moos¹⁶ Hansen's¹⁷ investigation led him to the view that the psychological situation has much to do with the reactivity which some patients exhibit to specific antigens to which they are sensitive Moreover he says "I cannot escape the impression in many cases that not infrequently a seemingly causal psychic alteration may be only coordinated with the somatic reaction, and that both are dependent on a mysterious third factor that escapes our detection It seems to me, for example, that not infrequently certain asthmatic individuals show to a more or less marked degree symptoms of manic-depressive disease, and that asthmatic attacks predominate in attacks of depression"

Support of Hansen's contention is furnished by Saxl¹⁸ who reports the case of a patient, who had suffered from migraine since early youth and had been subject to fluctuations of mood He was seized with attacks of bronchial asthma during the involutional period Some years later, perhaps precipitated by a further psychic trauma, he developed a manic-depressive state in the course of which five exacerbations were observed An attack of asthma subsided each time previous to the acute exacerbation of psychosis, only to return with its disappearance Oberndorf¹⁹ reports the analysis of an asthmatic in which he believes it was shown (1) that psychological stimuli set the attacks in motion, (2) that the so-called specific allergic determinants had nothing to do with the attacks, and (3) that after treatment the asthmatic attacks were substituted by emotional outbursts quite like manic episodes The patient, after treatment, ate chicken, corn and cabbage freely and was able to tolerate the presence of dogs and cats To all of these she exhibited positive skin reactions Fenichel²⁰ has attempted a more detailed description of the psycho-dynamic situation in asthma—stating that asthma is not an hysterical conversion symptom and that the asthmatic between attacks behaves like an obsessional neurotic In his book in which he devotes some ten pages to the subject, Fenichel places asthma between stuttering and psychogenic tic He assumes the existence of intrinsic respiratory eroticism and reduces the psychological process in asthma to a formula, of the validity of which I am on principle rather skeptical As to the therapy of asthma, Fenichel believes that the analyst's task is the radical treatment of the pregenital psychological structure which he believes underlies the

symptom. Quite properly Fenichel also mentions the intimate relationship that exists between anxiety and the function of respiration. In this connection he discusses the views of Hainik²¹ who finds the fear of suffocation a widespread phenomenon and relates it to castration anxiety of which he believes it to be a distorted expression. One of his patients, for example, imagined that the analyst might cut off his air supply by means of scissors. The second point derived from Hainik is that fear of being smothered underlies every fear of death and is in general the most archaic content of anxiety. He believes that this feeling, which may be experienced at the time of suckling, remains connected unconsciously with every later experience of a dangerous situation. I have at present under observation a young man who develops deep gasping respirations whenever his anxiety is aroused by matters touching on his social or economic inadequacy. All his life he has suffered from an acute sense of anxiety in any situation in which there was any suggestion of smothering—for example, if any one in fun would put a pillow on his head. The intimate relationship which exists between anxiety and respiration suggests the possibility that the constant variations in respiratory function are based in part, at least, upon constant unconscious responses to anxiety. It is my personal observation that the sensation which we recognize as anxiety is felt in the lower anterior thoracic wall and presents itself to us as a feeling of being unable to inspire freely. I suspect that it may arise in kinesthetic impulses from the diaphragm which may be related to its tonus. Christie²² believes that the incidence of respiratory disorder in neurosis is much greater than is generally supposed and that tracings taken by means of an ordinary recording spirometer are of value in the diagnosis and differentiation of certain types of neuroses. His cases fell into two groups: anxiety neuroses with irregular shallow type of respiration, and conversion hysterias, with a tendency to hyperventilation. This latter occurrence is consistent with sighing respiration which I have mentioned and to which Baker²³ has recently drawn attention. A thorough investigation of pulmonary volumes would be of interest in this connection.

As might be expected, the idea of "birth trauma" has found its way into discussion of the etiology of asthma. Freud has challenged the value of this hypothesis admirably in his recently translated "Hemmung Symptom und Angst." May I quote "The principal objection to be raised against it, however, (i.e. the birth trauma) remains the fact that it hangs in mid-air, instead of being based upon verified observation. For no trustworthy investigation has ever been carried out to determine whether difficult and protracted birth is correlated in indisputable fashion with the development of neurosis—indeed, whether children whose birth has been of this character manifest even the nervousness of earliest infancy for a longer period or more intensely than others. If the assertion is made that precipitate births, those easy for the mother, may possibly have for the child the significance of a severe trauma, then *a fortiori* it would certainly be necessary that births

resulting in asphyxia should produce beyond any doubt the consequences alleged. It seems an advantage of the Rankian etiology that it postulates a factor capable of being checked empirically, but as long as such a check has never actually been undertaken, it is impossible to estimate its real value." There is of course no reason why such an investigation could not be undertaken with special reference to asthmatics.

Closely related to this psychoanalytical hypothesis are certain recent physiological studies made in England by Barcroft²⁵ and in this country by Rosenfeld and Snyder²⁶ at the Johns Hopkins Medical School. These investigators have studied intra-uterine fetal respiratory movements. Barcroft's work began several years ago with an effort to answer the question "What sets off the birth process?" By a study of arterial oxygen saturation of goat fetuses he believes he has demonstrated increasing anoxemia as the fetal circulation no longer supplies the needs of the growing organism. A point is reached when, as Barcroft²⁷ put it "It gets so stuffy that the fetus moves out." If this is true then the amniotic sac is perhaps not the Nirvana which some psychoanalysts have led us to believe. States of tension and frustration may already be experienced in utero, and birth is not into a vale of tears, nor the prototype of all subsequent traumas, but rather a happy release. Barcroft demonstrated cinematographically the existence of rhythmic respiratory movements in fetal sheep and goats beginning as early as the thirtieth day, but curiously enough disappearing during the course of gestation. The occurrence of intra-uterine respiratory movements is not a newly discovered fact, having been observed by Preyer²⁸ as long ago as 1885. It received scant attention, however, until recently. Rosenfeld and Snyder have improved upon Barcroft's technic by eliminating the use of general anesthetics which they discovered depressed or completely inhibited intra-uterine respiration in the fetuses. Their observations were made on rabbits after section of the lumbar cord under local anesthesia. Fetuses within the intact uterus exhibited spontaneous respiratory movements characterized by rhythmic excursion of the thorax and abdomen. Although shallower, they resemble qualitatively the respiratory movements observed after birth. There is great variation in respiratory activity among different fetuses in the same uterine horn, some may be quiescent, others respiring at independent rates up to 60 per minute. No evidence was found that stimulation of fetal respiration occurs from oxygen want nor indeed from the administration of CO₂ to the mother. They regard the onset of post-natal respiratory activity not as an event initiated abruptly at birth but rather as a transition from the type of respiratory movement discernible during intra-uterine life. They do not support the view of Barcroft that the first breath of a newborn animal is caused by oxygen want. To be sure cyanosis often occurs in the newborn as the result of prolonged labor and the use of anesthetic agents in the mother—but, as has been said, whether this constitutes a psychic trauma to the child is still unknown. In the

absence of such knowledge it hardly seems fruitful to try to explain the disordered breathing of an asthmatic attack in terms of regression to the post-natal state

The condition of oxygen want naturally leads us to a consideration of pneumonia. There is more accurate knowledge about anoxemia in pneumonia than in almost any other disease. In spite of this, I know of no serious effort to correlate psychic changes in patients suffering from pneumonia with changes in the degree of anoxemia, though there have been comments on the decrease of restlessness and subsidence of delirium during oxygen therapy.

That the morbid picture is much influenced by anxiety states—fear of suffocation—fear of death, I have no doubt. A careful study of the events leading up to the infection would be of interest, as well as a study of the productions in delirium and the effects of more active suggestive therapy. C. Widmer²⁹ was aroused to an interest in this problem by events occurring after a fire in the Swiss hamlet of Tamins in which eight of those engaged in fighting the fire after drenching and exposure came down in from one to two weeks with attacks of severe pneumonia initiated by chills and soon followed by high fever and delirium. The patients lived at great distances from each other so that the doctor could not visit them all. In order to protect them from exposing themselves during their nocturnal delirium he was led to adopt the emergency measure of getting the patients out of bed at night and having them dress. He found to his amazement that the active delirial symptoms disappeared and that there occurred simultaneous clinical improvement. Apparently this experience caused him to investigate in the succeeding 10 years some of the psychological disturbances which he regarded as characteristic of pneumonia and which in his opinion were not related to the deliria of high fever nor to toxic exhaustive states. He found alteration in what might be called the integration of perception—a disturbance in the recognition of place, position, space, distance, division, rhythm, number, movement. This, according to Widmer, is the basis of the delirial state which may be present early in the disease and may be unrelated to the height of the fever or to any evidence of meningeal involvement. Since the patient's memory for recent events and his superficial contact with his environment may be unimpaired the existing delirium may at first escape detection. Widmer essayed to correct this state of confusion not by direct conscious psychotherapy since he found his patients lacking in insight and quite inaccessible, but by the expedient of getting them out of bed. Sometimes he had them sit in rocking chairs for as much as from four to six hours a day, even letting them take a few steps. By these and various other maneuvers he attempted to bring them back to a more normal relationship to their environment. He states that the procedure far from doing the patients harm led to normal sleep, to disappearance of delirium, to improvement in blood pressure and to moderation of toxic manifestations. Widmer's observations, of course, need corroboration, although it would

require some temerity to repeat them in this country where it is customary to keep the convalescent from pneumonia at rest in bed for at least a week after his temperature has returned to normal. Still I think it is apparent that these experiences if they are correctly reported are not without interest

In the beginning of this paper I spoke of the unwisdom of advocating such concepts as *psychogenic versus organic* as applied to the etiology of disease. It is my belief that any disease from hysteria to carcinoma or better any diseased individual may be studied legitimately and with profit by methods both psychological and organic. What we discover with these methods will be different sets of facts, in the one instance psychological facts, in the other, facts which have anatomical, chemical or physiological bearings. To correlate these will always be difficult—perhaps will be looked upon for the present as a *tour de force*. But such efforts seem to me to be of value. Our attitude toward disease is changing. It is no longer satisfactorily explained as a catastrophic invasion by noxious agents, a belief handed down to us not by bacteriologists alone but by our more primitive animistic ancestors. We know now that it requires more than the tubercle bacillus to make a man tuberculous, more than a specific antigen to produce an asthmatic attack and more than pneumococci to precipitate an attack of pneumonia. The other ingredient in the disease state was then thought to reside in the “reaction of the host,” by which was meant in his humoral and immunological defenses. There is now a growing body of evidence which leads to the belief that psychic influences as well play an important part in the process of falling ill, and that disease be it infectious, allergic, functional, organic or degenerative has its developmental history in which the whole personality is involved. To cultivate this field we must create new methods of personality study aided by the insight which psychoanalysis has given us.

CASE REPORTS

MARKED UREMIA WITH RECOVERY, REPORT OF A CASE*

By R O BOWMAN, Ph D , and S WOLPAW, M D , *Providence, Rhode Island*

CASE REPORT

J F, a 29-year-old white woman, was admitted to the Surgical Service of the Cleveland City Hospital on September 12, 1933

According to the patient's history her last menstrual period had occurred on July 8, 1933. Having missed her August period and believing herself to be pregnant she had attempted to produce an abortion by the use of various oral medications, the exact nature of which we were unable to determine. Failing in this attempt an abortion was induced on September 7, by packing the vagina with gauze. The pack was removed after one day and was followed by rather profuse vaginal bleeding. Twenty-four hours later the patient had a severe chill and felt feverish. She began to vomit rather copiously and it was called to her attention that her eyes had become yellow in color. These symptoms became increasingly severe until the time of her admission to the hospital.

The past history was negative except for four induced abortions during the past eight years, several of them followed by chills and fever. The patient had four living children.

Examination showed the patient to be well-nourished and acutely ill. The skin and sclerae were definitely jaundiced. There were no visible petechiae. The heart and lungs were normal. The blood pressure was 110 systolic and 60 diastolic. The abdomen was negative except for the liver which was just palpable at the costal margin. The spleen was not palpable. Pelvic examination revealed the cervix to be lacerated but firm. The uterus was enlarged, boggy and in a posterior position. There was tenderness in both fornices on motion of the cervix. There was no peripheral edema and the reflexes were physiological.

The temperature on admission was 37.8° C, the pulse 90, and the respirations 20. The blood urea nitrogen was 183 mg per 100 cc, the creatinine 18.6 mg per 100 cc, the carbon dioxide combining power 20 volumes per cent, the icteric index 63, and the hemoglobin 65 per cent (Sahli). A blood Wassermann was negative.

The clinical impression on admission was that of an incomplete abortion, and a toxic hepatitis and nephrosis with uremia. The latter lesions were attributed to the ingestion of an unknown drug.

Two days after her admission to the hospital the patient signed her release and was discharged against advice.

The patient was readmitted, this time to the Medical Service, on September 23, 1933, eleven days after her original admission. Her condition during this interval had become progressively and rapidly worse. At this time the history was obtained from the patient's husband that the abortion on September 7, 1933 had been attempted by placing two bichloride of mercury tablets against the cervix and packing the vagina with gauze. Samples of the oral treatment (Savatan capsules in their original box, several of which were missing and one broken in half) were also submitted.

* Received for publication November 18, 1936
From Cleveland City Hospital, Cleveland, Ohio

Examination at this time revealed the patient to be deeply jaundiced. She was extremely ill, toxic, disoriented, and had a watery and bloody diarrhea. The physical findings were not of great significance. The respirations were regular and very deep in character. The liver was not palpable. There was slight bilateral costo-vertebral tenderness. The temperature was 37° C, the pulse 90, and the blood pressure 110 systolic and 64 diastolic. There was no pericardial friction.

The laboratory findings on the day of this admission showed that the blood urea nitrogen was 352 mg per 100 cc (checked), the creatinine 24.3 mg per 100 cc (checked), the uric acid 14.4 mg per 100 cc, and the CO₂ combining power 14.5 volumes per cent.

The clinical impression on this admission was uremia due to bichloride of mercury poisoning, with hepatitis and nephrosis.

During the 10 days after admission the patient's condition remained critical. She was disoriented the greater part of the time. Her diarrhea continued with four to seven stools daily. Her urinary output when measurable varied between 250 cc and 750 cc a day. She developed a bilateral suppurative parotitis which required incision and drainage, and a bilateral acute otitis media which required myringotomy. Treatment consisted of usual routine measures for bichloride of mercury poisoning, 4000 cc of normal saline solution daily by clysis, imperial drink, sodium thiosulfate, and glucose given by mouth and intravenously. The anemia which became rather marked responded well to a 50 per cent solution of ferric and ammonium citrate. After two weeks her improvement was slow but steady and there were consistent changes in the urinary and blood chemistry findings. On 11-14-33 her blood urea nitrogen and creatinine were normal and the urine negative, with low specific gravity. Phenolsulphonephthalein excretion was 45 per cent in two hours and the average of two Van Slyke urea clearances (maximum clearance) was 63 per cent. A Mosenthal test run the next day showed average specific gravity of 1.014 for the day and the same figure for the night specimen. On 12-9-33 her blood urea nitrogen had risen slightly to 19.8 mg per 100 cc and a repeat urea clearance determination was 34 per cent of standard and 39 per cent of maximum. She was discharged from the hospital on 12-11-33, three months after her first admission, having nearly regained her normal weight. The chart gives the blood and urine findings during her hospital stay.

On 9-13-35 she was again admitted on the Obstetrical Service of City Hospital and was delivered uneventfully of a normal full-term child. Her post-partum course was not remarkable. Physical examination at this time showed no significant findings. Her blood pressure was 102 systolic and 64 diastolic. The urine was negative for albumin, sugar, cells and casts. The specific gravity was 1.008. The patient left the hospital by release before kidney function studies could be performed.

The patient was seen personally in February 1936, two and one-half years after her original admission. She refused further follow-up studies but stated that she had been quite well and able to do all of her own housework.

A search of the literature has failed to reveal a case of such marked uremia with recovery, and we feel that recovery here has been adequately proved by the ability of her kidneys to withstand pregnancy. Selman and Lengar,¹ from this hospital, have reported a case of asthmatic shock which recovered after developing a blood urea nitrogen of 142 mg per 100 cc and creatinine of 15.4 mg per 100 cc. Our case showed a much more severe blood picture, while the blood urea nitrogen is the highest seen by us in some 25,000 determinations.

We have no proof that this is a case of mercury bichloride poisoning. Only one sample of urine of less than 100 cc was examined for mercury on 9-26-33 and none was found. One would not expect to find it in such a small quantity of urine, particularly since the absorption and excretion from the vagina would

both be rapid, and small amounts of mercury are more toxic by this route. This same sample was negative for leucine and tyrosine crystals. Montzka² has reviewed poisoning with mercury by the vaginal route and reports a fatal case. Mintz³ has reported that 7.5 grains of mercury bichloride were fatal. The history here indicates double this dose was used.

The other possible etiological factor is the Savatan. The Bureau of Investigation of the American Medical Association has kindly supplied the information that Savatan contains the ecboic oils of tansy, mint and apiol.⁴ Brenot,⁵ whose original article we were unable to obtain, has reported a case of fatal poisoning with apiol with intestinal symptoms, icterus and uremia, but the dose which is toxic (0.6 to 0.8 gm.) would be improbable here since only eight and a half of the capsules had been taken. One of the important toxic actions of this drug is on the heart, yet at no time did this patient show any cardiac abnormalities. The hepatitis, which occurred rather early to be due to mercury, might have been caused by the ecboic oils.

SUMMARY

A case record is presented of a patient with marked kidney insufficiency probably produced by mercury bichloride per vagina, who recovered sufficiently on routine treatment to undergo a normal pregnancy two years later.

REPORT OF A CASE OF STATUS ASTHMATICUS WITH AUTOPSY

By JOSEPH R. WISEMAN, M.D., F.A.C.P., *Syracuse, New York*

CASE REPORT

Mrs. E. H., a housewife, aged 40, entered the University Hospital, October 16, 1935, complaining of severe asthma.

Her mother, aged 77, has arteriosclerosis. Her father died at 50 of heart trouble. One brother is living and well, no sibs have died. She has four living children, one of whom has diabetes for which insulin is taken, one child died at four of nephrosis. No allergic family history could be obtained. The patient lived in Syracuse, New York all of her life except for two trips to Florida in 1925 and 1927. In childhood she had measles, mumps, and varicella, jaundice in 1915, pleurisy twice (1918 and 1934), mild scarlet fever in 1927 with no complications. A goiter had been present for 27 years. There had been some swelling of the ankles for 11 years, most

* Received for publication November 5, 1936.

noticeable at night Since the attack of scarlet fever in 1927 she had been moderately short of breath

Previous hospital admissions 1919, Laparotomy—gall-bladder found to be normal, appendix removed 1934, Acute upper respiratory infection—asthma 1935 (March) Acute upper respiratory infection—asthma 1935 (May) Severe asthma

During her stay at the University Hospital in 1934 the following observations were made Hemoglobin 93 per cent, red blood cells 4,900,000, white blood cells 7,500, polynuclears 59 per cent, lymphocytes 33 per cent, large mononuclears 5 per cent, eosinophiles 3 per cent Other eosinophile counts were 0, 1 per cent and 5 per cent

The patient attended the Cardiac Clinic at the Syracuse Free Dispensary from July 3, 1934 to April 16, 1935 Numerous observations of the vital capacity, blood pressure and heart rate gave the following average readings vital capacity 2,475 c c, blood pressure 126 systolic and 85 diastolic, heart rate 86 The heart outlines were within normal limits and the sounds were clear She was discharged with a final diagnosis of "No organic heart disease—bronchial asthma"

She came to the Allergy Clinic at the Syracuse Free Dispensary July 31, 1934, and was under my observation until her last illness Her first asthmatic seizure occurred in September 1929, two years after an attack of scarlet fever For five years she has taken ephedrine every night and often has had to sit up in a chair The asthma was worse in winter and in rainy weather In the summer of 1934 from June to August she had considerable sneezing

More than 80 intracutaneous skin tests gave positive reactions to house dust, ragweed, feathers, wheat, lima bean, lamb and cocoa She was given advice as to environmental precautions and the elimination of suspected foods, and was treated by injections of house dust, ragweed and mixed stock respiratory vaccine At her visits to the clinic she appeared cheerful and optimistic and seemed to show some improvement but upon close questioning admitted one or more attacks of asthma requiring ephedrine practically every night At times her daughter gave her epinephrine by hypodermic She was placed upon a Rowe elimination diet for five weeks without relief On May 17, 1935, she had a severe attack of asthma, the tongue was said to be swollen and the face and hands blue She had to be carried downstairs in a rocking chair and was taken to the Onondaga General Hospital where she remained one week

Late in September 1935 she developed an acute upper respiratory infection which kept her in bed four days and caused a marked increase in the number and severity of the asthmatic attacks She became exceedingly weary and remained propped up in bed all of the time A hypodermic of epinephrine had always helped her but on October 16, she was unable to obtain relief, even from 1 c c She became faint and was sent by ambulance to the University Hospital, where she was placed on the medical service of Dr W D Ayer *

Admission examination A refined appearing woman of good nutrition and development, sitting up in bed, breathing with great difficulty, using all of the accessory muscles of respiration Pupils are equal and react to light and accommodation Some nasal discharge A few dental cavities Throat injected, tonsils cryptic Small goiter Lungs hyperresonant and filled with wheezing rales Heart enlarged to left with systolic and diastolic murmurs in the mitral area, and a diastolic blow at the left border of the sternum Sounds are regular in force, rate and rhythm Blood pressure 150 systolic and 90 diastolic Abdomen soft, operative scar present Liver and spleen not felt Reflexes hyperactive

During the five days of her hospital stay she presented the picture of continuous asthma which resisted all medication She took very little fluid by mouth and practically no food She went practically without sleep except for a few brief intervals

* I am indebted to Dr W D Ayer and to Dr E C Reifenshein, physician in chief, for the privilege of using the records of the University Hospital

FIG 1 Large bronchus (low power and high power) Infolding of mucous membrane Thickening and hyaline degeneration of basement membrane Inflammatory reaction and dilated vessels

when she became drowsy after a hypodermic of morphine. Ether and oil per rectum were not well retained and had little effect. Continuous oxygen therapy by tent was of little service. The diastolic murmurs noted at entrance were not heard thereafter. The pulse became more rapid, the skin cyanosed, the ankles edematous and the abdomen distended. Unconsciousness supervened, the temperature reached 108° ante mortem and the patient died from exhaustion on October 21, 1935.

She received iodide by mouth and vein, calcium gluconate, inhalations of epinephrine 1-100, ephedrine gr 3/8 with amytal gr 3/4 morphine by hypodermic gr 1/8 to 1/4 with and without atropine, 14 doses, a total of 2 5/8 grains, digitalis 9 doses, 13 1/2 grains. At first 1 c c doses of epinephrine were given by hypodermic, later 0.5 c c was administered at intervals of 15 to 30 minutes. In all 114 doses were given, about 2 1/2 oz in five days. Until just before death the temperature had varied from 98.6° to 101°, the pulse from 82 to 120, and the respirations from 20 to 30.

Following are the essential features of the autopsy by Dr. Robert O. Gregg and Dr. J. Howard Ferguson. Body is that of a fairly well developed, well nourished, middle-aged woman. There is apparently slight distention of the abdomen. There is slight edema of the ankles.

Pleural Cavities The lungs fill the cavities and meet across the midline when the thorax is opened and cover nearly the entire pericardium. There are no adhesions and no free fluid.

Thyroid The thyroid is symmetrically enlarged, but the trachea is not depressed.

Medastinum Without evident lesion.

Pericardial Cavity Contains approximately 10 c c of clear amber fluid. Pulmonary artery opened in situ is without evident lesion.

Heart Weight 275 gm. The right auricle is markedly dilated and filled with fluid blood. The ventricles are contracted. The auricular appendages are without evident lesion. The tricuspid, pulmonary and aortic valves are without evident lesion. There is some thickening along the line of closure of the mitral valve, particularly on the anterior cusp. The coronary arteries show a slight amount of yellowish thickening and seem to be soft throughout their entire extent. On section of the myocardium the muscle is deep reddish brown in color and rather firm in consistency. There are two small areas of whitish softening in the anterior wall of the left ventricle.

Lungs Weight of left 260 gm. Weight of right 260 gm. On section the lungs seem much more crepitant than usual. On pressure there seem to be scattered diffusely throughout both lungs numerous air-containing spaces up to 1/2 or 1 cm in diameter. The bronchi throughout both lungs, particularly in the lower lobes, are filled with thick tenacious mucus. The lungs are grayish pink in color throughout. Vessels and bronchial lymph nodes show nothing unusual.

Liver Weight 1500 gm. The liver substance is yellowish brown in color and somewhat firmer in consistency than usual. There appears to be a minimal amount of scar tissue throughout the entire liver structure.

Kidneys Weight 260 gm. The kidney substance is reddish brown in color throughout except for one area of rather grayish white color and firm consistency in the cortex of the left kidney. This area is approximately 1 cm in diameter and extends to the capsule. The capsules strip easily. The cortex and medulla have the usual relationship.

Adrenals Show nothing unusual.

Aorta Shows a minimal amount of yellowish thickening.

Anatomical Diagnosis Bronchitis. Marked pulmonary emphysema. Probable infarct of kidney.

Microscopical Diagnosis *Heart* Some fatty and Zenker's degeneration of myocardium. Slight fibrosis. *Liver* Slight fine scarring in areas. *Kidneys* Infarction.

Fig 2 Small bronchus (low power and high power) Mucous plug filling lumen Slight inflammatory reaction No change in basement membrane

with extensive, capillary thrombosis of glomeruli, marked tubular degeneration. *Lungs* Generalized emphysema with scattered areas of slight fibrosis with some infiltration of lymphoid cells. The larger bronchi show some infolding of the mucous membrane. In some areas the goblet cells are more prominent than usual. Other areas do not appear unusual. The basement membrane throughout shows rather marked thickening and hyaline degeneration. In the sub-epithelial connective tissue there is a diffuse infiltration of leukocytes consisting of lymphoid cells, plasma cells, and eosinophiles in about equal proportions. The small blood vessels in this area are unusually prominent. There are scattered capillary hemorrhages. The mucous glands are prominent but otherwise not unusual.

The smaller bronchi and bronchioles show less infolding of the mucous membrane. The basement membrane shows only scattered areas of thickening and very little hyaline degeneration. There is some infiltration of leukocytes in the sub-epithelial connective tissue. These cells are in about the same proportions as found in the larger bronchi. The blood vessels do not appear unusual. The lumina in many places are filled to a varying degree with rather dense mucoid material containing many lymphoid cells, plasma cells, and eosinophiles in about equal proportions. There is very little crystalline material seen.

Why did this woman go into status asthmaticus which resisted all treatment and led to death within a week? The exciting cause appeared to be an acute upper respiratory infection which produced a marked increase in the severity of her asthma. It is well known that infections of this type, popularly called colds, are the *bête noire* of numerous asthmatics, who may be quite comfortable in the intervals between these bouts of infection. The general population entertains these disorders in such large numbers, especially during the colder months of the year, that probably no striking decrease in their incidence can be brought about until a form of preventive vaccination, practicable on a large scale, can be developed.

Would altered treatment have resulted in her recovery? Undoubtedly the amount of epinephrine administered was very large—about $2\frac{1}{2}$ oz. within five days. May not this have caused an exhaustion of the glycogen reserve of the body, where almost no food was consumed? Epinephrine, particularly in large amounts, may have unfavorable side effects. Doses as high as 1 c.c. which were given to her for a time, may actually be harmful and should seldom be used save in acute emergencies. From 0.2 to 0.4 c.c. is probably best for the average attack, repeated in 20 minutes or as often as may be necessary. The action of epinephrine is rapid but not sustained, hence the rationale of frequent doses which are not too large. In asthmatics who have become refractory to subcutaneous injections, intravenous epinephrine may give startling relief. Inasmuch as powerful effects may follow intravenous injections the initial dose must be very small. I have seen an attack of asthma broken in an epinephrine refractory patient by as little as 0.1 c.c. of 1-10,000 epinephrine intravenously.

Did the administration of morphine contribute toward this patient's death? She received within five days 14 hypodermic injections totaling $2\frac{3}{8}$ grains. Not many physicians have seen asthma patients die following morphine administration, and case reports in the literature are uncommon. The statement is not infrequently made that morphine is dangerous in asthma and had better be withheld, but actual evidence bearing upon its action and results is scanty. Cohen and Rudolph¹ report that they have seen five patients with acute asthma in whom death followed within a few hours after morphine administration, and

FIG 3 Small bronchus (low power and high power) Mucous plug Prominent goblet cells Slight inflammatory reaction Little change in basement membrane

one case of death after codeine. The symptoms of asthma increased following morphine and the patients died respiratory deaths resembling strangulation. In two autopsied cases the entire bronchial tree was filled with a tenacious mucous exudate. The authors believe that

- 1 Morphine depresses the respiratory center and makes respiration more shallow

- 2 Abolition of the cough reflex makes it more difficult to expel mucous plugs

- 3 Opiates may cause a hive reaction in the bronchial tree

Jackson² states that morphine and other opium derivatives are able to produce bronchospasm by direct action upon the bronchial muscles, independently of the innervation, and that such a spasm is lasting and difficult to relieve by drugs with an opposing action such as epinephrine which stimulates the bronchodilator nerve endings. He raises the question as to the existence of two separate and distinct forms of bronchial asthma, the one of nervous, the other of muscular origin. Feinberg³ considers morphine idiosyncrasy rather frequent among asthmatics and that a fatality may be hastened or brought on by its use. Sollmann⁴ states that therapeutic doses of morphine produce slight bronchial relaxation whereas large doses cause marked constriction. "The relaxation may play a part in the relief of bronchial spasm (asthma), while the constriction may contribute to the asphyxia of toxic doses. The effects are peripheral for they occur on excised bronchial muscle." "The constrictor action is not antagonized by atropine and must, therefore, be on the muscle or myoneural junction." "Unless there is nausea the secretion of mucus appears diminished. This may be explained largely by the suppression of cough, permitting a longer sojourn of the mucus in the bronchi, with consequent removal of its water by absorption and drying, but there may also be a central depression." Personally I consider morphine a dangerous drug in asthma.

Would bronchoscopy have helped this patient? The finding of large amounts of tenacious mucus in the bronchial tubes and the knowledge that this is a common condition in severe asthma suggest that mechanical removal of the exudate would be exceedingly useful. The technical difficulties and possible danger of bronchoscopy in a seriously ill patient must be considered, but in some instances it will probably prove to be a life saving procedure.

Recently the inhalation of helium and oxygen has been suggested for the treatment of severe or intractable asthma. A mixture of oxygen 20 per cent and helium 80 per cent has one-third the density of atmospheric air and appears to enter narrowed air passages with much greater ease. Barach^{5,6} and Maytum et al.⁷ have had some very favorable experiences. In severe asthma where the patients had become refractory to epinephrine, the relief of the paroxysm was accompanied by a return to normal epinephrine sensitiveness. With five patients in status asthmaticus Barach believes that lives were saved. Cylinders containing helium and oxygen in proper percentages are now on the market, and the inhalation of this mixture gives promise of being a very useful therapeutic agent, deserving of further clinical trial.

The pathological changes noted in this patient have been described by other observers. Emphysema, large amounts of thick tenacious mucus in the bronchial tree, infolding of the epithelial lining, fibrosis, prominence of goblet cells and

mucous glands, thickening and hyaline degeneration of the basement membrane, infiltration of the tissues with eosinophiles, all are well known findings. Others have described in addition increased thickness of the walls of the bronchi, hypertrophy of the muscle layers, myositis of the bronchial muscles and adhesive pleuritis. Hueber and Koessler⁸ in their classical study of the pathology of bronchial asthma made very careful measurements of the bronchial tubes and came to the conclusion that the actual thickness of the walls of the bronchi and bronchioles of more than 0.2 mm. outside diameter is definitely increased.

Does a combination of the above described tissue changes indicate a characteristic pathology for bronchial asthma? Walzer⁹ has well summarized the position of those who take a negative stand. He states that there is no one significant abnormality present in every case of asthma nor are there any findings not met with in some other respiratory disturbance. He believes that the common secondary bronchitis and emphysema can cause increased thickness of the muscle layer and can produce most of the other changes. On the other hand Michael and Rowe¹⁰ and Alexander¹¹ have stated that a pathological picture characteristic of bronchial asthma does exist. Hueber and Koessler⁸ believed that the simultaneous occurrence of eosinophilia in the blood, sputum, and tissues does not occur in any other condition which could be confused with bronchial asthma.

SUMMARY

A case of status asthmaticus is reported. Death appeared to be due to cardiac and general exhaustion. The role of the administration of large amounts of epinephrine and of morphine is discussed. Bronchoscopy is recommended in selected cases. The inhalation of helium and oxygen is considered. The pathological findings are similar to those reported in other patients who have died in acute asthma.

EDITORIAL

THE PHYSIOLOGIC SIGNIFICANCE OF SWEATING

Human sweat glands, which according to Krause number about 2,380,000 are distributed over the entire surface of the body. Those in the axillary and inguinal regions are larger and of slightly different construction than are those situated elsewhere. The number in a specific region is greatest in the palms of the hands and the soles of the feet, next greatest in the forehead and least on the trunk and extremities. Kuno has reported that the extremities of Japanese, which are subjected to much exposure, contain a greater number of sweat glands than do the extremities of other races whose extremities are not exposed.

Sweating induced by heating the body occurs as a reflex mediated through the central nervous system and the sympathetic nerve fibers which supply the sweat glands. Langley, who first accurately described the secretory nerve fibers of animals, showed that they were part of the thoracolumbar or sympathetic division of the autonomic nervous system. He demonstrated that sympathetic nerves contained fibers which control vasomotor reactions and sweating. If the vasomotor fibers were completely removed, sweating could not be demonstrated. Later, he showed by operation on cats that the nerve fibers concerned with sweating corresponded to the segmental distribution of the sympathetic nerves in the spinal nerves. He showed further that the area of skin supplied by the gray rami of each ganglion corresponded largely with the area of skin supplied by the homologous posterior root fibers.

Langley's observations on cats are applicable to man, as recent studies following bilateral cervicothoracic ganglionectomy, bilateral lumbar ganglionectomy and bilateral ventral rhizotomy have confirmed this segmental distribution of the sympathetic nerve fibers to the sweat glands. As a result of these studies it is possible to determine by tests of sweating what part of the sympathetic nervous system has been interrupted or removed.

There has been much controversy relative to the centers which control sweating. Evidence has been advanced by various investigators that sweat centers are situated in the cerebral cortex, the hypothalamic regions, the medulla oblongata and the spinal cord.

From a study of lesions of the spinal cord which affected soldiers, Andre-Thomas concluded that spinal centers for the innervation of the sweat glands of the head, neck, upper extremities and upper portion of the thorax, were situated between the eighth cervical and the sixth thoracic segments, and that those for the innervation of the sweat glands of the lower part of the trunk and extremities were situated between the sixth thoracic and upper lumbar segments. Head and Riddoch have shown that sweating which ceases temporarily after removal of the impulses from higher centers by

complete transection of the spinal cord not only returns eventually but that it becomes excessive

Since sweating may be produced by mental effort, Kuno suggested that there might be a cortical center, and in confirmation of this, Guttman reported that sweating occurred in response to electric stimulation of the cerebral cortex. However, Kuntz suggested that sweating induced by stimulation of the cortex might be produced by secondary impulses to the autonomic center in the hypothalamus. Cushing's studies on man have demonstrated that excessive sweating can be produced by injection of solutions of posterior pituitary, or pilocarpine into the cerebral ventricles. Since sweating is a part of the mechanism for reducing body temperature, it is probable that the center which controls it is situated in the hypothalamic region where the center for the regulation of the body temperature apparently is situated.

The most commonly used methods for determining sweating are the starch-iodine method and the cobaltous chloride method. In both of these tests the estimation of the degree of sweating depends on the change in the color of the material applied to the skin. In the starch-iodine test, when the skin is dry, the powder remains white, with the presence of sweat the color of the powder becomes deep blue-black. In the cobaltous chloride method, when the skin is dry the area to which the solution has been applied is deep blue in color but turns red on the appearance of sweat.

• Sweating, which is a normal physiologic response, varies greatly among different individuals and under varying conditions. The reactions of the excretion of sweat are very sensitive to psychogenic factors, as is seen by the response to pain, gastrointestinal cramp, anxiety, joy, and the administration of nicotine. It is said that, in general, obese people, those who eat excessively, and those who have hyperthyroidism sweat excessively. Sweating is also increased in some cases of hemiplegia, herpes zoster, tuberculosis, hyperpituitarism, in most fevers, and in vasomotor disturbances such as Raynaud's disease. However, little clinical significance can be given to the presence of increased perspiration in any of these conditions. An example of marked increase in local sweating is that which affects the extremities without evidence of peripheral vascular disease. In some cases the hyperhidrosis in the hands and feet is so marked that it produces maceration of the skin and is disabling to a large degree. Adson, Craig, and Brown were of the opinion that this condition is a dysfunction of the sympathetic nervous system, which originates in the higher cerebral centers.

Diminution of sweat may occur in cases of poliomyelitis, multiple sclerosis, syringomyelia, myelitis, tumor of the spinal cord, and orthostatic hypotension. Since orthostatic hypotension is a disease which affects the vasomotor nerves and also the fibers that control sweating, the anhidrosis which occurs in orthostatic hypotension is of definite clinical importance. It is one of the characteristic abnormalities of the syndrome. Chew, Allen and Barker have reported anhidrosis to be present in 17 out of 21 cases. This lack of sweating varies in extent of distribution more or less with the

severity of the orthostatic hypotension. Anhidrosis also may occur as a result of degeneration of the sweat glands. Fog reported a case in which it followed a long standing febrile illness and biopsy of skin revealed that only about half of the sweat glands were present while the other half had undergone degeneration. A few cases in which generalized anhidrosis was due to congenital and general developmental anomaly of the skin have been reported.

Following the advent of surgical procedures on the sympathetic nervous system, it was found that anhidrosis produced by the interruption of the sympathetic pathways to a given cutaneous area is permanent. This provided a method for determining the distribution of the sympathetic nerve fibers to the sweat glands. Since hyperhidrosis was presumably the result of dysfunction of the sympathetic nervous system, sympathetic ganglionectomy was performed for the relief of this condition. The first two surgical interruptions of the sympathetic pathways for hyperhidrosis were made in 1921 by Kotzareff and in 1928 by Braeucker. In 1932 and 1934 Adson, Craig and Brown reported six cases of essential hyperhidrosis in which sympathetic ganglionectomy produced permanent relief. White has treated one patient who had hyperhidrosis, by paravertebral injection of alcohol into the upper thoracic ganglions, the sweating was definitely subnormal at the end of a year.

Although a great amount of investigative work has been done and considerable information has been obtained concerning the distribution of the sympathetic fibers to the sweat glands, the situation of sweat centers and the physiology of sweating in man, the clinical use of this knowledge is limited. According to Brown, the response of the secretion of sweat to a high environmental temperature determines the presence or absence of generalized or localized forms of anhidrosis, hypohidrosis or hyperhidrosis, and sweating tests will demonstrate whether complete denervation of the sympathetic fibers to a given area is present after sympathectomy. Repetition of the sweating tests at later intervals determines whether regeneration of nerve fibers has occurred. Clinically, anhidrosis is an important characteristic abnormality of orthostatic hypotension and surgical interruption of the vasomotor pathways will produce permanent relief in cases of hyperhidrosis.

REVIEWS

The Comparative Anatomy of the Nervous System of Vertebrates Including Man
By C U ARIENS KAPPERS, M D, the late G CARL HUBER, M D, and ELIZABETH
CAROLINE CROSBY, Ph D 2 volumes, 1845 pages The Macmillan Co, New York
City 1936 Price, \$16 00 per set

The names of the authors of this important work are adequate guarantee of ability to handle an admittedly difficult subject Started over ten years ago as a translation of Kappers' German text on the same subject, it soon outgrew the status of a translation and blossomed as a full fledged new work based upon the combined studies of both the senior and junior authors with such additions from other sources as seemed requisite to cover the broad scope of the work

It may be stated at the outset that this book is not for the general practitioner of medicine or for those not familiar with neuro-anatomical structure and the technique of its investigation and presentation But as a reference work, of which more will be said later, and for those concerned in neuro-anatomy and its application, it is a gold mine of information

The work consists of two volumes of about 850 pages each In spite of its size it is almost literally a glorified abstract of the subject matter covered, rather than an exhaustive discussion of any of the multiple subdivisions into which it divides itself This is necessarily so because of the breadth of the subject itself

The first volume discusses the phylogenetic development of the neurone, the spinal cord, the medulla oblongata in its broad sense, including the pons and the cerebellum The structural significance of the spinal cord of each Class is discussed beginning with Amphioxus and ending with man The same phylogenetic sequence is observed in describing the medulla oblongata, but here the subject is discussed in functional systems which are traced through the various Classes Taste and tactile sensibility are first described, followed by the lateral line and vestibulo-cochlear afferent systems each being carried through the ascending forms of the vertebrate filum The efferent motor system is similarly treated, including those motor centers resident in the midbrain The organization of the reticular formation is then discussed Under this head an unusual definition of the "final common path" is presented with a completely erroneous reference to Sherrington (1906) as the basis of the definition The correlative function of these reticular centers is clearly demonstrated, but their acceptance as a final common pathway in the original sense of Sherrington is much to be doubted An excellent discussion of the cerebellum concludes this volume

Volume II treats of the midbrain and diencephalon as a unit to which about one-fourth of the volume is dedicated The remaining three-fourths is devoted to the telencephalon The analysis of the telencephalon is divided into two parts The first takes up the non-mammalian forms, describing them in serial order up to the mammal The latter is also included in this grouping except for the nonolfactory cortex This subject is reserved for a special chapter in which it is treated in considerable detail The discussion of the fundamental structure of the forebrain as determined by embryological evidence is regrettably lacking in completeness in that it does not include Kingsbury's (1920, 1922) interpretation of this process, particularly so since this author's findings are at variance with those favored in this book, though none-the-less have been widely accepted elsewhere A somewhat similar criticism may be made regarding the otherwise splendid discussion of the cerebral cortex in which the illuminating recent findings from the laboratories of Yale are conspicuous by their absence This is explainable on the basis of the lapse of time since the inception of the work now under review though the omission seems hardly to be justified on this basis

Each chapter of the book contains a resume of the subject matter treated of in the chapter. This is arranged under subtitles indicative of the Classes under consideration and is an important and valuable feature of the book. The chapter ends with a bibliography pertaining to the chapter and arranged under subtitles like that of the resume preceding it. Thus the seekers of bibliography in the lateral line system of Plagiotomes, or a like subject treated of in this book can in a moment locate the object of his search. These subject classification references consume in all about 250 pages and constitute in themselves a justification for the publication of the work.

Woven throughout the text are examples of the thesis of neurobiotaxis so closely associated with the name of the senior author, on the basis of which apparently disharmonious anatomical conditions of different species are harmonized and their significance interpreted.

The seven hundred plus illustrations adequately cover the text but the appearance of many of them is marred by indifferent labeling and the almost complete lack of descriptive technic in the legends limits their intelligent interpretation to those who are completely familiar with neuro-histological technic. This is a pity. A compensation exists, however, in the profusion of illustrations which the authors and publisher have managed to crowd into this work and still hold its publishing price at an astonishingly low figure. This is something for which an appreciative public will undoubtedly give thanks.

These volumes fill a want which has long existed in the English language and will remain as a worthy monument to the industry and genius of those who have produced them, one of whom, Dr G. Carl Huber, unfortunately did not live to witness this climax to a busy and fruitful career.

C L D

Recent Advances in Diseases of Children By WILFRED J. PEARSON, D.S.O., M.C., D.M., F.R.C.P., and W. G. WYLLIE, M.D., F.R.C.P. 566 pages, 14.5 × 20.5 cm. Third Edition. P. Blakiston's Son and Co. Inc., Philadelphia, Pennsylvania 1935. Price, \$5.00.

The title "*Recent Advances in Diseases of Children*" does not correctly state the subject matter of this edition. In reality an attempt has been made to offer the general practitioner brief accounts of the illnesses of the young in a manner in which they are met in every day practice. The authors are concerned with the subjects primarily from a clinical aspect, important scientific data are mentioned if they are an aid clinically.

Certainly one of the assets of this book is its excellent organization which will make it helpful to the general practitioner. One is also impressed, however, by the lack of scientific discussion and of adequate references.

W M S

The Principles of Bacteriology and Immunology By W. W. C. TOPLEY, M.A., M.Sc., F.R.C.P., F.R.S., Professor of Bacteriology and Immunology, University of London, and G. S. WILSON, M.D., F.R.C.P., D.P.H., Professor of Bacteriology as Applied to Hygiene, University of London. London School of Hygiene and Tropical Medicine. Second Edition. 1645 pages, 18.5 × 25 cm. William Wood and Co., Baltimore. 1936. Price, \$12.00.

The years that have passed since the publication of the first edition of this book have been years of renewed activity in research in the field of bacteriology and immunology. This has made necessary no inconsiderable revision of the text. A number of chapters have been rewritten, many have had much new material added, and hardly one has been left without partial revision. Several new chapters have been

included. All of this has been accomplished without greatly enlarging the book by a discreet omission of some of the older work and by a judicious selection from the newer. Nevertheless, its publication in a single volume in response to former criticisms would seem to make for inconvenience in reading. The second edition will undoubtedly maintain the same position as the first in the forefront of texts on the subject.

F W H

Chemical Procedures for Clinical Laboratories. By MARJORIE R. MATTIC, A.B., Sc.M. 520 pages, 16×24 cm. Lea and Febiger, Philadelphia, Pa. 1936. Price, \$6.50.

This is a comprehensive manual for chemical clinical laboratories. The author has included methods for the determination of the various constituents of blood, urine, feces, cerebro-spinal fluid and other body fluids. The chapter dealing with the chemical treatment of transudates and exudates is to be commended. The book should be valuable to those laboratories inexperienced in extensive work of this nature for the author has incorporated precautions and helpful changes in many determinations and has included only those methods which she has found satisfactory in her own laboratory. In other laboratories the book will be acceptable only in part since many of these methods will be neither suitable nor sufficiently recent for their use.

E M R

Cancer Committee Studies. California Medical Association. 123 pages. J. W. Stacey, Inc., San Francisco, California. 1936. Price, \$7.50.

The book is paper bound and of small portfolio, with 123 pages. It contains the report of a cancer commission created by the House of Delegates of the California Medical Association in 1931. This commission appointed sub-committees to report on all phases of cancer therapy and in all specialties. The book is a timely one and should be read by every person interested in the cancer problem.

The first chapter is on Radiology. The Radiological Committee treats the question of "Radiology in the Treatment of Cancer," in a very safe and conservative manner. Following this, each special subject is reported upon by its own committee.

The great value of this book lies in the fact that it is not based on the experience of one man, nor one institution. "The Commission has made what it believes to be the first organized attempt to set forth the opinion of the medical profession rather than that of any one individual or clinic, or even one specialty." The purpose of the study is "to develop a better agreement in the profession and a wider diffusion of knowledge of the diagnosis and adequate treatment of early cancer." This aim has been closely adhered to and the book contains much valuable knowledge carefully compiled. The most up-to-date opinions about symptoms, onset, methods of diagnosis, treatment of early cancer, etc., are set forth, and where there is a controversy of opinion, especially as to treatment, both methods are given and the reasons for them stated. This book is a valuable adjunct to any physician's library.

COLLEGE NEWS NOTES

GIFTS TO THE COLLEGE LIBRARY

Grateful acknowledgment is made of the receipt of the following donations to the College Library of publications by members

Books

- Dr Russell L Cecil, Fellow, New York, N Y, "Diagnosis and Treatment of Arthritis",
- Dr Henry A Christian, Fellow, Boston, Mass, two autographed books, "The Diagnosis and Treatment of Diseases of the Heart" and "Medical Papers," the latter being a volume containing contributions dedicated to Dr Christian
- Dr E B Krumbhaar, Fellow, Philadelphia, Pa, an autographed copy, "Clio Medica XIX Pathology",
- Dr Edward C Mason, Fellow, Oklahoma City, Okla, an autographed book "Why We Do It",
- Dr William D Nimelh, Fellow, Mexico City, D F, a book of poems by Dr Nimelh

Reprints

- Dr Dean B Cole, Fellow, Richmond, Va, three reprints—"The Treatment of Pulmonary Tuberculosis" (with Walter L Nalls, M D), "Ambulatory Pneumothorax" (with Edgar C Harper M D), "Therapeutic Use of Iodized Oil in Pulmonary Disease" (with Edgar C Harper, M D),
- Dr Lewis B Flinn, Fellow, Wilmington, Del, one reprint—"Preliminary Observations on the Clinical Use of Zinc-Protamine-Insulin in Out-Patients",
- Dr Cecil M Jack, Fellow, Decatur, Ill, one reprint—"Some Unusual Features of Lung Cancer",
- Dr Hubert C King, Fellow, Lakewood, Ohio, one reprint—"Prognosis in Coronary Heart Disease and After Coronary Occlusion",
- Dr Sinclair Luton, Fellow, St Louis, Mo, one reprint—"Clinical Use of Digitalis Variables Encountered",
- Dr Theodore H Morrison, Fellow, Baltimore, Md, one reprint—"Idiopathic Ulcerative Colitis with a Report of an Unusual Case",
- Dr Albert E Russell, Fellow, Washington, D C, one copy of the Second Annual Memorial Lecture, "Silicosis and Other Dust Diseases",
- Dr Louis J Bailey, Associate, Detroit, Mich, one reprint—"Paralysis of the Third Cranial Nerve Due to Spontaneous Hemorrhage Within the Nerve in the Latter's Intracranial Course" (with E S Gurdjian, M D),
- Dr Samuel Morrison, Associate, Baltimore, Md, six reprints—"The Pharmacopeia and the Physician" (with Julius Friedenwald, M D), "The Treatment of a Lung Abscess Due to *Bacillus Coli* with a Lytic Filtrate" (with Raymond E Gardner, Sc D), "The Elimination of Various Dyes From the Pavlov Pouch of Dogs" (with David L Reeves, M D and Raymond E Gardner, Sc D), "The History of the Development of the Stomach Tube With Some Notes on the Duodenal Tube" (with Julius Friedenwald, M D), "The Medical Treatment of Peptic Ulcer" (with Julius Friedenwald, M D), "Value, Indications, Limitations and Technic of Colonic Irrigation" (with Julius Friedenwald, M D),
- Dr William Kendrick Purks Associate, Vicksburg, Miss, seven copies of reprint—"Total Thyroidectomy for Heart Disease",

Dr William R Wirth, Associate, New Orleans La, one reprint—"The Significance of Cardiac Arrhythmias as Encountered in General Practice"

Miscellaneous

- Dr Robert E Schlueter, Fellow, St Louis, Mo, a photograph album containing photographs of the pilgrimage to William Beaumont's grave by the American College of Physicians during its 1937 Session in St Louis,
 Dr John A Shuman, Fellow, Los Angeles Calif, two lectures on "Southern California Medicine, Indian to Spanish Inclusive",
 Rev Harvey K Heebner, Editor, The Schwenkfeldian, Philadelphia Pa a copy of "A Memorial to Dr James M Anderson" (Master),
 Mr M R Kneiff, Executive Secretary, Catholic Hospital Association, St Louis, Mo, one copy, "Special Directory Number of *Hospital Progress*"

At the last annual meeting of the State Medical Association of West Virginia, the following members of the College were elected to office Dr Charles W Waddell (Fellow), Fairmont, W Va, President, Dr Arthur A Shawkey (Fellow), Charleston, W Va, Second Vice President, Dr T M Barber (Associate), Charleston, W Va, Treasurer

Commander Eben E Smith (Fellow), Medical Corps, United States Navy, has relieved Commander Louis H Roddis (Fellow), Medical Corps, United States Navy as editor of the "United States Naval Medical Bulletin" and as secretary of the Postgraduate Board

During the Centennial Celebration, Davidson College, on June 8, conferred the honorary degree of Doctor of Science on Lieutenant Colonel James Stevens Simmons, Medical Corps, United States Army, now stationed at the Army Base, Boston Mass, in recognition of his investigations on tropical diseases and preventive medicine

At the eighty-seventh annual meeting of the Illinois State Medical Society, held in Peoria, May 18-20, Dr Samuel E Muson (Fellow and Governor for southern Illinois) was elected President-Elect of the Society

Dr Louis F Bishop, Jr (Fellow), New York, N Y, recently attended, as a guest speaker, the West Virginia State Medical Association meeting in Clarksburg. He addressed the West Virginia Heart Association, May 24, on "Bundle Branch Block", the Section on Internal Medicine, May 24, on "Fugitive Arrhythmias", and the General Assembly, May 25, on "Prevention of Heart Disease"

Dr Frank Burge (Fellow), Philadelphia, Pa, has been appointed Editor-in-Chief of "Diseases of the Chest," official journal of the American College of Chest Physicians. Dr Burge is also an Associate Editor of Chest Diseases of the Cyclopedia of Medicine

The American College of Chest Physicians is the new name adopted by the Federation of American Sanitaria, the change in name being adopted at Atlantic City during June

Dr Sinclair Luton (Fellow), St Louis, Mo, presented a scientific exhibit on "Major Errors Involved in the Use of Droppers for Liquid Digitalis Preparations" at the eightieth annual meeting of the Missouri State Medical Association during May

Dr Roy S Leadingham (Fellow), Atlanta Ga, presented a scientific exhibit and paper on "Rat Bite Fever" at the meeting of the American Society of Clinical Pathologists in Philadelphia, June 2-5

The Fifth International Congress of Radiology will convene at the Palmer House, Chicago, September 13-17, 1937. It will be the first time that the world leaders in the medical and scientific development field of roentgen-ray and radium have met in America. The American Roentgen Society, the American College of Radiology, the Radiological Society of North America, and the American Radium Society will merge their meetings with the International Congress. "The Unity of Medicine" will be the theme of the entire Congress. Leaders in other branches of medicine will participate. More than 250 scientific papers will be read. They will be delivered in each lecturer's own language, but will be flashed on screens in English, German and French, as the papers are read.

The General Secretary of the Congress, Dr Benjamin H Orndoff (Fellow), is in charge of the headquarters at 2561 North Clark Street, Chicago. Dr George E Pfahler (Fellow), Philadelphia, is one of the honorary vice-presidents.

Dr Nathan B Van Etten (Fellow), New York, N Y, Speaker of the House of Delegates of the American Medical Association, addressed the general assembly of the Minnesota State Medical Association at St Paul May 4, on 'Medical Care for All Americans'.

At the fifteenth annual meeting of the Philadelphia Heart Association, Dr William D Stroud (Fellow) was reelected President, Dr David Riesman (Fellow) was elected Vice President, Dr Thomas M McMillan (Fellow) was elected Secretary, and Dr Edward B Krumbhaar (Fellow) was elected a member of the Board of Governors.

Dr William E Robertson (Fellow) was inducted as President of the Philadelphia County Medical Society on July 1. Dr Louis H Clerf (Fellow) has been elected a Director.

Dr E J G Beardsley (Fellow) Philadelphia, Pa, was elected Secretary-Treasurer of the American Association of the History of Medicine at the last annual meeting of that organization at Atlantic City during May.

Dr David Riesman (Fellow) received the honorary degree of Doctor of Laws from the University of Wisconsin at commencement June 21, 1937.

At the 131st Annual Meeting of the Medical Society of the State of New York, held at Rochester, N Y, May 24, 25, 26, 1937, Dr William A Groat (Fellow), Syracuse, N Y was elected President-Elect of the Society.

Dr Dwight O'Hara (Fellow), Professor of Preventive Medicine in Tufts College Medical School, has been appointed to the newly created position of vice-dean, to supervise clinical instruction in the third and fourth years.

Dr Alfred Friedlander (Fellow), Professor of Medicine and Dean at the University of Cincinnati College of Medicine, has been appointed superintendent of the General Hospital to fill the vacancy caused by the death of Dr Henry H Langdon. Dr Friedlander will continue his work in the medical school and act as superintendent only until a successor for the latter position can be found.

The American Association for the Study and Control of Rheumatic Diseases held its fourth annual meeting at Atlantic City under the presidency of Dr Russell L Cecil (Fellow), New York City. Dr Cecil presented a paper on "The Necessity of Certain Criterion for the Diagnosis and Cure of Rheumatic Arthritis", Dr Bernard L Wyatt (Fellow), Tucson, Ariz, gave a paper on "Experimentally Induced Jaundice", Dr Philip S Hench (Fellow) Rochester, Minn, gave a paper on "Further Observations of the Effect of Jaundice on Atropic Arthritis and Fibrositis"

Dr Lewellys F Barker (Fellow), Baltimore, Md, discussed the "Progress of Endocrinology" at the twenty-first annual meeting of the Association for the Study of Internal Secretions at Atlantic City in June, under the presidency of Dr F M Pottenger (Fellow), Los Angeles

Dr Paul D White (Fellow), Boston, Mass, delivered the Alvarez Lecture on "The Differential Diagnosis of Cardiac and Gastro-Intestinal Disorders," before the fortieth annual meeting of the American Gastro-Enterological Association at Atlantic City in June, under the presidency of Dr Chester M Jones (Fellow), Boston, Mass

Dr Lewis A Conner (Fellow) New York City, delivered the annual Henry Jackson Lecture of the New England Heart Association, April 30, on certain aspects of rheumatic fever and rheumatic heart disease

Dr Walter M Boothby (Fellow), and Dr William A Plummer (Fellow), Rochester, Minn, addressed the annual meeting of the American Association for the Study of Goiter, held in Detroit, June 14-16, on "Interpretation of Basal Metabolic Rates in the Relatively Normal Individual"

Dr George A Harrop (Fellow), Baltimore, Md, has been appointed Director of Research on the staff of E R Squibb & Sons, according to a recent announcement. Dr Harrop has been Assistant Professor of Medicine at Johns Hopkins University School of Medicine. E R Squibb & Sons are constructing a new research laboratory at New Brunswick, N J. "Investigation along scientific lines will be carried on without necessary regard to its immediate practical outcome. It is also planned to undertake active clinical investigation with which to supplement and give orientation to the laboratory studies"

Dr Horace W Soper (Fellow), Dr Frank D Gotham (Fellow), and Dr Lee Pettit Gay (Fellow), have been elected President, Vice President and Treasurer, respectively, of the recently formed Missouri Chapter of the National Society for the Advancement of Gastro-Enterology

The following Fellows were selected to present graduate lectures in connection with the twenty-first annual course of medical lectures and clinics of the University of Washington from July 19-23. Dr Anton J Carlson, Professor of Physiology, University of Chicago, Dr William S Middleton, Professor of Medicine, University of Wisconsin Medical School, Madison, Dr Hans Lissel, Clinical Professor of Medicine, University of California Medical School, San Francisco

Dr Mary Riggs Noble (Fellow), Philadelphia, Pa, was elected Treasurer of the American Medical Women's Association at its meeting in Atlantic City in June

Dr Jay A Myers (Fellow), Minneapolis, Minn, was elected President of the National Tuberculosis Association at its annual meeting, June 2

Dr Ross M Chapman (Fellow), Towson, Md, was installed as President of the American Psychiatric Association at its annual meeting in May

Dr Hugh B Campbell (Fellow), Norwich, Conn, has been elected President-Elect of the Connecticut State Medical Association Dr Charles F Turkington (Fellow), Litchfield, is President during the present year

Dr William R Brooks (Fellow), Fort Smith, Ark, has been elected Secretary of the Arkansas State Medical Association for the coming year

OBITUARIES

DR JOHN WYCKOFF

The sudden death of Dr Wyckoff (Fellow) on June 1, 1937, at the age of 55 years, removed from this scene, in the prime of life and at the height of his professional career, one of the most widely beloved and respected members of the profession in New York City

Born in Tindivanam, India, of Dutch Reform American Missionary parents, he spent two years in undergraduate study at Rutgers College, which institution later (1920) conferred upon him an honorary M A degree and still later made him a Trustee

He was graduated in 1907 from the New York University and Bellevue Hospital Medical College and served his internship in Bellevue Hospital After spending some time in various clinics in Germany he returned to New York to take up the practice of internal medicine In 1914 he was married to Miss Elizabeth Crane Porter of Claverock, New York, who with his three children survives him

Almost immediately after his return from study abroad he was made an Instructor in Medicine in the New York University school, in which he rose successively to the ranks of Clinical Professor, Associate Professor and finally (1932) Professor of Medicine To his responsibilities as head of the department of medicine were added about the same time the onerous duties of Dean of the School

He served successively as Adjunct Assistant Physician, Assistant Physician, and Physician and Director of the Third Medical Division of Bellevue Hospital, in which institution much of his professional life was spent

One of the very first of the efforts directed toward the special care and rehabilitation of heart patients was the Bellevue out-patient cardiac clinic, established in 1911 by Dr Hubert V Guile Two or three years later Dr Wyckoff became associated with Dr Guile in this clinic and, upon the

retirement of the latter in 1919, was made its head. Under his skillful guidance the clinic became one of the important agencies of the city for the training of physicians in heart diseases.

The special interest of Dr. Wyckoff in diseases of the heart was expressed in many ways. His writings were chiefly upon different aspects of this subject. For a long time he served as Chairman of the Heart Committee of the New York Tuberculosis and Health Association and of the Association of Cardiac Clinics. He was a Director, and later President, of the American Heart Association. In all of these capacities his work was characterized by the same unusual degree of energy, enthusiasm, vision and judgment that marked his services to the medical school and that played so important a part in the rapid development of that school. Indeed, it is given to few men to show such a record of successful achievement in so many fields of medicine as John Wyckoff could show.

His memberships included those in the New York County and State Medical Societies, American Medical Association, New York Academy of Medicine (Trustee, 1936), Association of American Physicians, American College of Physicians, Interurban Clinical Club, American Clinical and Climatological Association, American Association for the Advancement of Science, Association of American Medical Colleges (President, 1936).

But the mere listing of his accomplishments, appointments and connections would give a sadly inadequate picture of John Wyckoff the man. The things which won for him the deep affection and admiration of his fellow physicians and many friends were not so much his brilliant accomplishments as the personal qualities of modesty, honesty, courtesy, fair-mindedness and consideration for others. The world is much the poorer for the passing of John Wyckoff.

The above information has been supplied by Dr. Lewis A. Conner, F.A.C.P.

C. F. TENNEY, M.D.,
Governor for Eastern New York, New York

DR. DOUGLAS BROWN

Dr. Douglas Brown (Fellow), Veterans' Administration Facility, Castle Point, N. Y., died June 6, 1937, at the age of sixty-seven.

Dr. Brown was born in New York City, later removing to Pottstown, Pa., where he attended the public schools. He attended the Sheffield Scientific School of Yale University, later entering Columbia University College of Physicians and Surgeons and graduating with the M.D. degree in 1894. In his early experience he was House Physician to the Fourth Division of the Bellevue Hospital, and Clinical Assistant in Neurology at the Vanderbilt Clinic, both of New York City. During 1908 and 1909 he served under General Gorgas at the Ancon Hospital, Panama. In 1910 he took post-graduate work at the Allgemeines Krankenhaus, Vienna, in Pathology, Bac-

teriology, Internal Medicine, and Diagnosis. He entered the U. S. Veterans' Administration and served on various assignments over the United States being classed as Internist-Expert in the Veterans' Administration.

Dr. Brown made numerous contributions to the literature. He was a member of the New York County Medical Society, the Medical Society of the State of New York, the American Medical Association, the Association of Military Surgeons, the Medical Veterans of the World War, the American Public Health Association, and had been a Fellow of the American College of Physicians since 1924.

DR. HAROLD BUNCE MYERS

Dr. Harold Bunce Myers (Fellow) of Portland, Oregon, died March 16, 1937, aged 50 years, of coronary thrombosis. At the time of his death he was Professor of Pharmacology and assistant dean of the Medical Department of the University of Oregon, having held both positions for more than 20 years. He took his bachelor's degree in the University of Wisconsin and graduated in medicine at Western Reserve University in 1911. He practiced a short time in Wisconsin and then went to New York where he was a member of the faculty at Bellevue Medical College, coming to Oregon in 1915 as head of the department of Pharmacology.

He had a keen interest in the welfare of medical students, and through contact with all applicants for admission to the school, had a closer acquaintance with the student body than others of the faculty. In many instances students received material aid through anonymous sources, because of his efforts. His activities in the university were many and his counsel was much appreciated.

His scientific contributions were numerous and research work in his department was wisely guided by him. He was a member of many scientific societies.

T. HOMER COFFEN, M.D., F.A.C.P.,
Governor for Oregon

DR. JOHN OSCAR ELROD

Dr. John Oscar Elrod (Fellow), Forsyth, Georgia, aged 59, died in a private hospital in Macon, Ga., on April 21, 1937. He was a native of Adairsville, Bartow County, and had practiced medicine in Monroe County and the adjoining counties for thirty-seven years. He attended the North Georgia Agricultural College and later graduated from the Atlanta College of Physicians and Surgeons, Atlanta (now Emory University School of Medicine), in 1901. He did post-graduate work in medicine and pediatrics at the New York Postgraduate Medical School in 1903.

Dr. Elrod served as major in the Medical Corps of the Georgia National Guard. He served on various committee assignments and in offices of the Medical Association of Georgia, being its president in 1924-25. For

a number of years and until the time of his death, he was a member of the State Board of Medical Examiners. Dr. Elrod was a member of the Monroe County Medical Society, Southern Medical Association, American College of Physicians and the American Medical Association. He was one of the most aggressive and loyal friends of organized medicine, also to his professional, civic and religious duties. Surviving him are his widow, two daughters, Mrs. Carlton Mobley, Atlanta, Miss Mildred Elrod, Forsyth, a brother, G. D. Elrod, Atlanta, his mother, Mrs. G. B. Elrod, Adairsville.

GLLENVILLE GIDDINGS, M.D., F.A.C.P.,
Governor for Georgia

DR. DANIEL FRANCIS DALEY

Dr. Daniel Francis Daley (Fellow), Kingston, Pa., who had been in failing health for many months, died on April 24, 1937. He was born July 16, 1887, in Monmouthshire, Wales. His parents immigrated to this country when the future physician was an infant and his boyhood was spent in Luzerne, Pa., where he attended St. Mary's Academy. At an early age young Daley began to work in and about the coal mines and later through industry, loyalty and persistence in self-education, he was advanced to the responsible position of Chief Clerk of the Temple Coal Company.

Many youths would have considered that the far too early ending of formal education would prove a grievous handicap, but this lack acted as a stimulus in Daniel Daley's life and, without neglecting his duties to his employers, he established and carried out an admirable system of self-education at home. He completed a course of study far more extensive and intensive than many colleges require of their students and, having selected the profession of medicine as a career, he was accepted for entrance in the Jefferson Medical College of Philadelphia where he, in 1915, received his M.D. degree.

Dr. Daley served his internship in the Mercy Hospital, Wilkes-Barre, Pa., in which institution he later was to become pathologist.

Dr. Daley was an indefatigable student. He pursued his studies in the clinics of this country and abroad.

He was a member of the Philadelphia Pathological Society, the American Society of Clinical Pathologists and became a Fellow of the American College of Physicians in 1928.

Dr. Daley was a "good doctor." He was respected by fellow physicians and loved by his patients.

E. J. G. BEARDSLEY, M.D., F.A.C.P.,
Governor for eastern Pennsylvania

DR. EUGENE F. McCAMPBELL

Dr. Eugene F. McCampbell (Fellow), Columbus, Ohio, died May 8, 1937, of pneumonia at the age of fifty-five. Dr. McCampbell was born at

Marysville, Ohio, in 1883. He received the degree of Bachelor of Science in 1906 and the degree of Doctor of Philosophy in 1911 from the University of Chicago. His medical training was received at Rush Medical College, from which he graduated in 1912.

Dr McCampbell was a teacher for a number of years previous to the time he studied medicine. He was Instructor in Bacteriology at the Ohio Medical University from 1903 to 1904, Assistant in Pathology at the University of Wisconsin during 1905 and 1906, Instructor in Bacteriology, 1906-08, Associate Professor of Bacteriology, 1908-10, Ohio State University College of Medicine. He served as Professor of Bacteriology, 1910-13, Professor of Preventive Medicine, 1913-27 and Dean, 1916-27, of the Ohio State University College of Medicine. He was Assistant in Pathology at the University of Chicago during the summers of 1908-11, Secretary and Executive Officer of the Ohio State Board of Health, 1912-16, Pathologist to the Columbus State Hospital, 1909-11. He had been a President of the Columbus Academy of Medicine and also a member of the Ohio State Medical Association, the American Medical Association, and had been a Fellow of the American College of Physicians since 1926. At the time of his death, he was a member of the Staffs of the Mount Carmel, Giant and White Cross Hospitals.

Dr McCampbell was the author of a number of publications, including "Laboratory Methods for Study of Immunity" and co-author of "General Bacteriology."

DR EARL B SWEET

Dr Earl B Sweet, Fellow, died May 22, 1937, in Los Angeles following an operation on May 19. Dr Sweet was born May 4, 1875, in Sloan, Iowa. He came to Los Angeles in 1887 and had his general education in the Los Angeles City Schools. He received his medical education at the University of Pennsylvania from which he was graduated in 1898. Dr Sweet returned to Los Angeles to practise, early limiting his work to that division of effort which comes under Internal Medicine. He was a fine upstanding man, well known to his colleagues and with a wide and friendly acquaintanceship in the community. He was a charter member of the University Club. He belonged to his County, State and the American Medical Associations and the Southern California Medical Association. Though those who knew him realized that he was failing during the last few months, his cheeriness and hope remained with him until the last two weeks when he realized what he had to meet. In his death the community and the profession lost a fine man and member, they send their sympathy to his widow, who survives him.

EGERTON L. CRISPIN, M D , F A C P ,
Regent

MINUTES OF THE BOARD OF REGENTS

ST LOUIS, MO

April 18, 1937

A regular meeting of the Board of Regents was held at the Jefferson Hotel, St. Louis, April 18, 1937, with Dr. Ernest B. Bradley, President, presiding, Mr. E. R. Loveland acting as secretary, and with the following Regents present:

Ernest B. Bradley, *President*,
James H. Means, *President-Elect*,
O. H. Perry Pepper, *First Vice-President*,
David P. Barr, *Second Vice-President*,
Walter L. Biering, *Third Vice-President*,
William Gerry Morgan, *Secretary-General*,
William D. Stroud, *Treasurer*,
William J. Kerr,
Roger I. Lee,
Sydney R. Miller,
George Morris Piersol,
G. Gill Richards,
Robert A. Cooke,
James B. Herrick,
Hugh J. Morgan,
James E. Paulin,
Egerton L. Crispin,
James Alex. Miller,
Francis M. Pottenger,
Charles H. Cocke,
Maurice C. Pineoffs,

and with Dr. Alfred Stengel as acting chairman of the Committee on Constitution and By-Laws.

Abstracted Minutes of the preceding meeting of the Board of Regents were read by the Executive Secretary, and, on motion, approved and read.

President Bradley announced that he had appointed a Committee to confer with the American College of Surgeons, his Committee consisting of the President, President-Elect and First Vice-President.

The Executive Secretary then read communications from Dr. E. W. Gehring, Governor of the College for Maine, dealing with the future policy of the College with respect to requirements of admission and the certification of physicians by the American Board of Internal Medicine, a communication from Dr. H. B. Logie, Executive Secretary of the National Conference on Nomenclature of Disease, thanking the College for its contribution to that organization's work, and a communication from Dr. James D. Bruce, Regent, expressing the opinion that the American College of Physicians should continue to admit to its membership those practicing specialties affiliated with Internal Medicine and also expressing doubt as to the advisability, at the present time, of making certification by the American Board of Internal Medicine a prerequisite to membership.

President Bradley read a communication from Surgeon General Reynolds of the U. S. Army and a reply by Dr. James Alex. Miller, concerning the Harlow Brooks' memorial. Dr. Miller explained that a fund is being raised to be used by a committee in the memory of Dr. Brooks for the cause of medical education. He recommended that if the idea of co-operating appeals to the College either approving the plan, or making a contribution, a general resolution to that effect could be adopted.

On motion by Dr Roger I Lee, seconded by Dr James E Paulin, and regularly adopted, it was

RESOLVED, that the Board of Regents appoint Dr James Alex Miller, a committee of one, to investigate the Harlow Brooks' Memorial Fund, and to report at some subsequent time to the Board of Regents for the appropriate action

In subsequent discussion, it was pointed out that the College is much interested in the project, but not prepared to make a contribution to the Fund

Dr William Gerry Morgan, Secretary-General, was called upon for his report. He reported the deaths of the following members since the last meeting of the Board of Regents

Master

| | | |
|-----------------|--------------|------------------|
| Smithies, Frank | Chicago, Ill | February 9, 1937 |
|-----------------|--------------|------------------|

Fellows

| | | |
|---------------------------|----------------------|-------------------|
| Bartley, Elias H | Brooklyn, N Y | January 12, 1937 |
| Busby, James Leslie | Pasadena, Calif | February 18, 1937 |
| Crane, Augustus Warren | Kalamazoo, Mich | February 20, 1937 |
| Fales, Louis Henry | Livermore, Calif | February 13, 1937 |
| Fraser, Benjamin H | Lexington, Ky | March 5, 1937 |
| Ghrist, David Garrison | Los Angeles, Calif | February 3, 1937 |
| Hodges, J Allison | Richmond, Va | December 15, 1936 |
| Johnston, Collins H | Grand Rapids, Mich | December 29, 1936 |
| Laubaugh, Ernest E | Boise, Idaho | December 13, 1936 |
| McKelvy, James P | Pittsburgh, Pa | January 28, 1937 |
| Mink, Owen J | M C, U S Navy | October 21, 1936 |
| Niemeyer, Charles Vincent | Union City, N J | January 11, 1937 |

| Plummer, Henry S | Rochester, Minn | December 15, 1936 |
| Redfern, Thomas C | Winston-Salem, N C | October 16, 1936 |
| Rich, William Lafayette | Salt Lake City, Utah | November 17, 1936 |
| Stearns, William G | Winnetka, Ill | January 11, 1937 |
| Waples, Frank A | Houston, Tex | March 3, 1937 |
| Warren, Luther Fiske | Brooklyn, N Y | January 18, 1937 |
| Wegge, William F | Milwaukee, Wis | November 20, 1936 |
| White, William A | Washington, D C | March 7, 1937 |

Associate

| | | |
|---------------------|--------------|------------------|
| McCalla, Randolph L | Boise, Idaho | October 10, 1936 |
|---------------------|--------------|------------------|

Dr Morgan further reported the following additional Life Members since the last meeting

| | |
|-------------------------|--------------------|
| William Eugene Kendall | Oak Park, Ill |
| Manfred Kraemer | Newark, N J |
| James W Hunter, Jr | Norfolk, Va |
| Herbert B Smith | Corning, N Y |
| Fresenius Van Nuys | Weston, Mass |
| George M Settle | Baltimore, Md |
| Edward B Vedder | Washington, D C |
| Robert A Peers | Colfax, Calif |
| Joseph D Condit | Pasadena, Calif |
| Charles W Stone | Cleveland, Ohio |
| Samuel A Vogel | Buffalo, N Y |
| Mills Sturtevant | New York, N Y |
| Russell M Wilder | Rochester, Minn |
| Cornelius Oliver Bailey | Los Angeles, Calif |

At this point, President Bradley called for resolutions on the deaths of certain of our former Officers and members. Resolutions had been presented both by Dr Robert A Cooke and Dr James Alex Miller on the late Dr Luther Fiske Warren. Dr Cooke presented the following resolution:

LUTHER FISKE WARREN

"The American College of Physicians records the death of Dr Luther Fiske Warren on January 18, 1937, with sorrow and regret.

"Dr Warren became a Fellow of this College in 1919, was chosen one of its Governors in 1931, and served as Regent from 1933 until his death. He was actively interested in the work of the College and served on several committees, especially the important Committee on Credentials.

"Dr Warren prepared for his professional career at the University of Michigan, where he received his medical degree in 1909. His talent for teaching was recognized at once, and he served the Department of Medicine at Michigan until 1912, when he was invited to come to the Long Island Medical College, where he rose rapidly to become Professor of Internal Medicine, which position he filled with distinction from 1917 until his death.

"In addition to his work as a teacher, he filled an important place on the staff of many of the hospitals of Brooklyn and Long Island, and he brought wise counsel, clear vision and sound judgment to his many spheres of activity, and he was an outstanding influence in his community.

"A great understanding, kindly sympathy and complete devotion to the highest ideals of his profession commanded the affection and respect of those in this College with whom he came in contact, and in his death we have lost an honored colleague and a beloved friend. Therefore, be it

"RESOLVED, that the American College of Physicians records its sincerest and deepest sorrow in Dr Luther Fiske Warren's death, its appreciation of his noteworthy services to his community and his profession, and, as a token of the esteem in which his memory will be held by the College, it is directed that this memorial be made a permanent record in the archives of the American College of Physicians and that a copy be sent to the members of Dr Warren's family."

—ROBERT A COOKE, M.D., F.A.C.P.

Dr James Alex Miller presented the following resolution:

LUTHER FISKE WARREN

"Dr Luther Fiske Warren died at his home, 81 Pierrepont Street, Brooklyn, N. Y., on January 18, 1937. Long the head of the Medical Department in the old Long Island College Hospital and after its recharter in 1930 in the Long Island College of Medicine, Dr Warren made his influence felt far beyond the confines of that institution.

"He was born in 1885 in Waterford, Mich. Working his way through school and college, he received his degree in Arts from the University of Michigan in 1907 and his M.D. from the same institution in 1909, attaining to membership in two honorary societies, Sigma Xi and Alpha Omega Alpha. For three years after graduation he remained at his Alma Mater serving as instructor in Clinical Microscopy and in Medicine.

"In 1912 he was called to Long Island as Assistant Professor of Medicine, being promoted to Associate Professor in 1915, and taking the Chair in Medicine in 1917, for a year as Acting Professor, and as full Professor in 1918. Besides directing the Medical Department of the College Hospital, Dr Warren was Physician-in-Chief at St. Johns Hospital and Medical Director of the Brooklyn Home for Consumptives. He was Consulting Physician to the Lutheran, the Coney Island, the Methodist Episcopal Hospitals and the South Side Hospital at Bayshore.

"Dr Warren was a brilliant clinician and teacher, and was endowed with vision and drive to an unusual degree. Among his many extramural activities should be listed the

Presidency of the Kings County Medical Society in 1930, Chairmanship of the Public Health Committee of the Brooklyn Chamber of Commerce, Directorship in the same organization, Directorship of the Brooklyn Council for Social Planning, and Chairmanship of the Brooklyn Health Council. He was a Trustee of the Polytechnic Institute and of the Packer Collegiate Institute. He was a Fellow of the New York Academy of Medicine, and a member of the American Medical Association, the American Heart Association, the National Tuberculosis Association, the Association for the Study of Internal Secretions, the American Society of Tropical Medicine and the American Society for the Advancement of Science.

"Dr. Warren was a Fellow of the American College of Physicians since June 19, 1919, he served as Governor for Eastern New York from 1931 to 1933 and as a Regent from 1933 to the date of his death. His counsel and advice have been of the greatest value to the Board of Regents in shaping the policies of the College. The Board of Regents very deeply mourn his loss and his absence from the Council Table will be very keenly felt, consequently, it is

"RESOLVED, that this Minute in the memory of Dr. Luther Fiske Warren be recorded in the records of the American College of Physicians in appreciation of his services to the College and to the medical profession and that a copy of this Minute be sent to members of his family

—JAMES ALEX. MILLER, M.D., F.A.C.P."

On motion seconded and regularly adopted, it was

RESOLVED, that the above resolutions be adopted and spread upon the Minutes of this meeting

Dr. William Gerry Morgan, as Secretary-General, then presented the following four resolutions on the late Dr. Harlow Brooks, Dr. Ernest E. Laubaugh, Dr. Frank Smithies and Dr. William Alanson White, which, by resolution unanimously adopted, were spread upon the Minutes of this meeting

HARLOW BROOKS

"Whereas, it was the rare good fortune of the American College of Physicians to have had Doctor Harlow Brooks associated with it in membership throughout a period of twenty-three years, and to have enjoyed and profited by his active personal participation and interest in its scientific and other activities

"His broad viewpoint and comprehension of medical problems, and the literary charm and forcefulness of his addresses and papers made his frequent and willing contributions to its programs of unexcelled value to the College. This value was greatly enhanced and enriched by the background of his personality in their presentation and his associations with its membership. Doctor Brooks was a man of great personal charm and friendliness, affable and lovable, a joy and an inspiration, and universally admired, esteemed, and beloved by his associates. The College not only shares in the loss to science and to humanity of this great and good man, but also suffers personal bereavement in the passing of a worthy and beloved personal friend

"And whereas, it is fitting that the College record a testimonial of its appreciation of the life work and character of Doctor Brooks, of its happy personal relations with him over many years, and of its sorrow over his passing, together with an expression of its sympathy with the bereaved family

"BE IT RESOLVED, that we express our deep sorrow for the loss of this true physician and wise counselor

—WILLIAM GERRY MORGAN, M.D., F.A.C.P."

ERNEST E. LAUBAUGH

"Whereas, the American College of Physicians has lost, in the death of Dr. Laubaugh, one of its most devoted Fellows

"Dr Laubaugh died at Boise, Idaho, on December 13, 1936. He was born in Pennsylvania in 1887, and was graduated in medicine from the Medico-Chirurgical College in 1909. After internship at Mercy Hospital in Pittsburgh and later in the Philadelphia General Hospital, he became a member of the Faculty of his Alma Mater. In 1913 he resigned to accept the post of Bacteriologist with the Idaho State Board of Health, a position he held until 1917. At the time of his death, Dr Laubaugh was a member of the Staff of St Alphonsus and St Luke's Hospitals in Boise.

"Dr Laubaugh retired from the World War as Captain in the Army. He was a member of a good many medical and scientific societies and had made notable contributions to medical literature.

"And Whereas, Dr Laubaugh was a former Governor of the College for the State of Idaho and took a keen interest in its welfare and upbuilding.

"BE IT RESOLVED, that the Regents express profound regret for the loss the College has sustained through the death of Dr Laubaugh, and the sympathy which is felt for the bereaved family of the deceased.

—WILLIAM GERRY MORGAN, M D, F A C P "

FRANK SMITHIES

"Whereas, Doctor Frank Smithies passed to his Eternal Home on February 9, 1937, at the age of 56 years. He was born in Elland, England, coming to the United States at the age of 5 years.

"Doctor Smithies was elected to Fellowship in the College in 1917, and throughout the subsequent years he was very active in the participation of its growth and development.

"Doctor Smithies gave unspiringly of his time and energies to the work of the College. To his foresight and directing influence does the College owe not merely its very existence, but the sane lines of its progress.

"Therefore BE IT RESOLVED, that the American College of Physicians through its Board of Regents express the profound regrets and deep sorrow for the loss of this highly valuable and interested Master, who had served as Regent, Secretary-General and President.

—WILLIAM GERRY MORGAN, M D, F A C P "

WILLIAM ALANSON WHITE

"Whereas, Dr William Alanson White died on March 7, 1937, in Washington, D C, in his 67th year.

"Dr White was elected to Fellowship in 1923, and was keenly interested in the progress and welfare of the College. As Superintendent of St Elizabeths Hospital at Washington, he had under his supervision more than six thousand insane patients and over one thousand employees, as well as a large staff of expert physicians. The responsibilities incident to directing such a large and complex institution rendered it impossible for him to attend all of the Annual Meetings of the College, which was a source of profound regret to him.

"Dr White was a man of innate kindness, always ready to extend a helping hand to all who sought his aid. He was universally admired and beloved by his immediate associates, the profession at large and by many in all walks of life.

"And Whereas, it is fitting that the College express its appreciation of the life work and character of Dr White, of his influence for the betterment of his fellowmen, and of its sorrow at his death, together with an expression of its sympathy with the bereaved family.

"Therefore BE IT RESOLVED, that we express our profound sorrow for the loss of this distinguished physician from our membership.

—WILLIAM GERRY MORGAN, M D, F A C P "

Dr George Morris Piersol presented the following resolution on the late Dr James M Anders, which, upon motion unanimously adopted, was spread upon the Minutes of the meeting.

JAMES M. ANDERS

"It is with deep sorrow and regret that we record the death of our distinguished past-president (1922), Dr James M. Anders, of bronchiopneumonia on August 29, 1936

"Dr Anders was a native of Pennsylvania, born on July 22, 1854. After a careful preliminary education he was graduated from the Medical School of the University of Pennsylvania in 1877. His subsequent career proved him to be a worthy son of that celebrated Class which furnished so many outstanding men to the medical profession of this country. The year he graduated in medicine, Dr Anders also received his Ph.D. His early interests centered about the biological and medical sciences. The original investigations which he conducted into certain plant functions earned for him recognition by the French Government, which made him an Officier de l'Instruction Publique et des Beaux Arts.

"Dr Anders attained his greatest distinction, however, in his chosen field of Internal Medicine and Public Health, for which he prepared himself thoroughly by many years of active affiliation with a number of Philadelphia's leading hospitals.

"As a teacher Dr Anders exhibited exceptional ability. In 1889 he became associated with the Medico-Chirurgical College of Philadelphia. By 1893 he had been made Professor of the Theory and Practice of Medicine and Clinical Medicine in that institution—a position which he graced with distinction for twenty-five years.

"Dr Anders' interest in public health and tuberculosis prevention led him to take an active part in civic affairs. From 1914 on he served as a member of the Board of Health of Philadelphia. He became a leading figure in many local, state and national health movements.

"One of Dr Anders' outstanding achievements in medical education was the role he played in bringing about the merge of the Medico-Chirurgical School with the University of Pennsylvania, which resulted in the present Graduate School of Medicine at Pennsylvania. He took an active part in the development and direction of this institution, serving until his death as one of its managers and, through his broad vision and enthusiasm, contributing in no small measure to its growth and success.

"Dr Anders was a prolific scholarly and popular author. In addition to innumerable original articles, he contributed to medical literature his large work on the "Theory and Practice of Medicine," which went through fourteen editions and later a text-book on "Medical Diagnosis." Not content with medical writings, Dr Anders wooed the Muse of poetry, publishing in 1934 a delightful volume, entitled "Meditations in Verse."

"As a reward for his accomplishments in medicine, public health and education, Dr Anders received numerous honorary degrees, was made a Chevalier of the Legion of Honor of France in 1923, and the same year had the distinction of being the first Fellow of this College to be made a Master.

"The crowded, varied, but fruitful career of Dr Anders was marked by signal successes. As a doctor, teacher, author, educator and public spirited citizen, he has earned the gratitude of his chosen City of Philadelphia and left an indelible imprint upon the progress of American Medicine.

—GEORGE MORRIS PIERSON, M.D., F.A.C.P."

Dr Svdnev R. Miller, Chairman of the Committee on Credentials, reported that his Committee had held two meetings—one on March 14, 1937, and one on April 18, 1937. At the meeting on March 14, the credentials of sixty-two candidates for Fellowship were examined. Of this number the Committee recommended the rejection of four, deferment of thirteen for further material time or investigation, and the election of forty-five. Of those recommended for election, thirty-nine were for advancement from Associateship and six for direct election. In one case, a candidate had served a five-year Associate term from 1931 to 1936, but because of critical illness was unable to qualify in the five-year period, and had been dropped. The Committee, however, credited his five-year Associate term and included his name among those for advancement now.

At the meeting of March 14, the Committee examined the credentials of eighty-seven candidates for Associateship, of which they recommended the rejection of ten, the deferment of six and the election of seventy-one.

At the meeting of the Committee on April 18, they considered the credentials of fifty-two candidates for Fellowship, of which they recommended forty-seven for election, one for election to Associateship, and four for deferment for further credentials.

At the meeting on April 18, they also considered fifty-seven candidates for Associateship, of which they recommended forty-seven for election, six for rejection and four for deferment.

The combined recommendations for election of the Committee on Credentials, as included in lists of names passed around for inspection by the Board of Regents, included ninety-two Fellows and one hundred and nineteen Associates.

Upon motion by Dr. Robert A. Cooke, seconded by Dr. Maurice C. Pineoffs, and regularly carried, it was

RESOLVED, that the following candidates shall be and are herewith elected to the respective class of Fellowship or Associateship as recommended:

Elected to Fellowship

| Name | City and State |
|-------------------------------|------------------------|
| 1 Archamberault, Charles Pahl | M C, U S Navy |
| 2 Arkin, Aaron | Chicago, Ill |
| 3 Baehr, George | New York, N Y |
| 4 Baer, Ridgely Waters | Frederie, Md |
| 5 Barry, Michael William | Omaha, Nebr |
| 6 Bergstrom, Victor William | Binghamton, N Y |
| 7 Bernton, Harry Saul | Washington, D C |
| 8 Bishop, F Warner | New York, N Y |
| 9 Boots, Ralph Henderson | New York, N Y |
| 10 Brand, Alonzo Frederick | Fayetteville, N Y |
| 11 Chapman, Edward Northrop | Colorado Springs, Colo |
| 12 Clark, Cyrus J | Indianapolis, Ind |
| 13 Cole, Rufus | New York, N Y |
| 14 Collins, Russell Johnson | East St John, N B, Can |
| 15 Cooke, William Clifford | San Diego, Calif |
| 16 Cooksey, Warren B | Detroit, Mich |
| 17 Curran, Jean A | Brooklyn, N Y |
| 18 Dale, Grover Cleveland | Goldsboro, N C |
| 19 Davies, Willard John | Rockville Centre, N Y |
| 20 DeGraff, Arthur Christian | New York, N Y |
| 21 de la Chapelle, Clarence E | New York, N Y |
| 22 Denny, Earl Rankin | Tulsa, Okla |
| 23 Du Bois, Eugene Floyd | New York, N Y |
| 24 Duggan, LeRoy Bates | Houston, Tex |
| 25 Ecker, Lewis Charles | Washington, D C |
| 26 Ensign, Dwight Chester | Detroit, Mich |
| 27 Fearon, Henry Dana | Brooklyn, N Y |
| 28 Fischer, Carl Castle | Philadelphia, Pa |

Dr Sydney R Miller, as Chairman of the Committee on Credentials, further reported that they recommend to the Board of Regents that the name of Dr Fernando Ocaranza, of Mexico, D F, be dropped from the Roster of Fellows, because he had failed to take up his election to Fellowship by the payment of the prescribed fees and dues in accordance with the By-Laws

On motion by Dr Sydney R Miller, seconded by Dr James E Paullin, and regularly carried, it was

RESOLVED, that the name of Dr Fernando Ocaranza, Mexico, D F, be dropped from the Roster of Fellows because of failure to take up his election in accordance with the Constitution and By-Laws

Dr Sydney R Miller, as Chairman of the Credentials Committee, presented the following resolution which had been unanimously adopted by his Committee at their meeting in Philadelphia on March 14

RESOLVED, that reconsideration of the proposed amendments to the Constitution and By-Laws be gone into by the Board of Regents before being proposed at the Annual Session

President Bradley explained that the members of the Credentials Committee have a very deep interest in the question of changes in the standards of admission anticipated by amendments proposed at the December, 1936, meeting of the Board, and felt particularly that the provision that certification should be a prerequisite for Associateship should be reconsidered, also the matter of "affiliated specialties"

On motion by Dr Bierring, seconded by Dr Means, and regularly carried, the resolution presented by the Committee on Credentials was adopted

There followed open discussion concerning the amendments proposed to the Constitution and By-Laws at the Regents' meeting during December, 1936

Dr James Alex Miller expressed regret that Dr Jonathan C Meakins, a member of the Committee on Constitution and By-Laws, was not present to join in the discussion. Dr Miller said that he thought it premature to put the proposed amendments into effect, for the reason that the question of certification of internists has not yet been established on a firm footing. If the Credentials Committee continues as it has in the past to closely scrutinize the credentials of every candidate, and even to more carefully investigate their credentials, the College may proceed on its present basis, giving the American Board of Internal Medicine more time to get established. The College should at least preserve its independence of action, and in his opinion the Board might do well to withdraw both the proposed amendments until some later time.

Dr Walter L Bierring, Chairman of the American Board of Internal Medicine, dis-

cussed the proposed amendments adopted during December, 1936, and suggested that certification might more properly be made a prerequisite for Fellowship, rather than for Associateship. He reported that to that date eighty-six applicants had applied for the examinations of the Board, and prophesied that in three or four years the Board may be called upon to examine about two hundred candidates a year, which is about the same as the number of elections to Fellowship in the College.

In part, Dr. Biering said "The type of Fellows of the College would be such as had been certified as internists under the proposed newer regulations. It is difficult to formulate any kind of a plan that would include distinguished men who would not come under the head of certified internists, whom we would feel honored to have made Fellows of this College, whether they were in an allied field or not, and it seems to me they should be in, if they can qualify. But, the American College of Physicians is an association of internists, as we understand it, and we feel that we might approximate somewhat to the standards and ideals of the Royal College of England and Scotland, if an examination is one of the qualifications for election. It is true that these Colleges also elect to Fellowship obstetricians, pediatricians, neurologists and other allied branches of Internal Medicine, not surgical."

Chairman Bradley pointed out that at the present time the American College of Physicians is not for internists only, but for those engaged in internal medicine and allied specialties.

At this point, Dr. Alfred Stengel, Acting Chairman of the Committee on Constitution and By-Laws, was called upon to make a report.

After discussing various considerations that had been presented to the Committee, Dr. Stengel summed up his remarks by saying that "it was the recommendation that the Board of Regents withdraw from the proposed amendments altogether at this time, because they feel the action is premature."

Dr. Stengel pointed out that another proposal had been received by the Committee, namely, to make provision for the legalization of alternates for the members of the Board of Governors who may be unable to attend the Annual Meetings. The following amendment had been formulated by Dr. Jonathan C. Merkins, the Chairman of the Committee:

"Any member of the Board of Governors unable to attend the Annual Session shall appoint as his alternate, with all the privileges of a Governor, a Master or Fellow of his district who will be in attendance at that Session. Upon presentation to the Chairman of the Board of Governors of a certificate of appointment, the alternate shall be recognized and act in the full capacity of Governor for the Session to which he has been appointed. The same alternate shall not be appointed for more than two consecutive years."

This amendment had not previously been presented to the Board of Regents for approval.

Dr. Stengel recommended that if the other recommendations for alterations in the Constitution and By-Laws are to be laid on the table for the present, it might be well to defer action also on the above proposal until another year.

On motion by Dr. Walter L. Biering, seconded by Dr. Sydney R. Miller, it was

RESOLVED, that the Board of Regents, after thoroughly studying the situation, withdraw the proposed amendments to the Constitution and By-Laws as considered at the December, 1936, meeting of the Board and subsequently published in the "Annals of Internal Medicine", and, further, any other amendments for action at the Annual Business Meeting during the current year.

In the discussion of the resolution, Dr. Maurice C. Pincoffs said in part, "These amendments have been read by all the members. That need not influence the Board in any way, but I think the motion before the house is something I favor, but I would like to present one point about it before we act, namely, there are a number of other solutions to these problems. We can make the certification a necessity or prerequisite for election for Fellowship

for men who are practicing Internal Medicine, and put up some other qualifications for those who are practicing affiliated specialties. Many of these affiliated specialties have Boards of their own, and we could equally well make it necessary for candidates from those specialties to present certification by their Boards before being elected by the College, so that we do not implicate or do not necessarily commit the College not to admit men in these other specialties, when we demand that those who are internists be certified. I feel certain that if we do not require our Fellows at least to be certified, before any great lapse of time, we would be withdrawing support from the American Board of Internal Medicine, an organization that we have sponsored."

Dr O H Perry Pepper recommended that there should be published in the "Annals of Internal Medicine" some explanatory statement concerning the action taken by the Board of Regents.

There followed discussion among the Regents generally concerning an official statement to the members at the Annual Business Meeting.

The following resolution was also regularly adopted:

RESOLVED, that a Committee of three, consisting of the President, Dr Walter L Biering, Chairman of the American Board of Internal Medicine, and Dr Maurice C Pincoffs, Editor of the ANNALS, shall be empowered to draw up an explanatory statement of the action of the Board of Regents for presentation to the members at the Annual Business Meeting.

Dr O H Perry Pepper, Chairman of the House Committee of the College, reported verbally that minor alterations and final furnishing had been completed since the last meeting of the Board of Regents, and that the balance from the appropriation made at the December meeting amounted to \$617. He said the Committee felt that the building is completed, that it is completely furnished, and that the Committee might well be discharged, the continued care of the building being left in the hands of the Treasurer and the Executive Secretary.

The Executive Secretary, Mr Loveland, said that he felt the Committee might very well be continued, for it would be helpful to have an official Committee with whom to consult.

On motion, seconded and regularly carried, it was:

RESOLVED, that the House Committee be tendered the thanks of the Board of Regents for their work, and that the Committee be continued.

President Bradley then asked Dr Stengel if there were any additional reports to be presented by the Committee on Constitution and By-Laws.

Dr Stengel stated that the only matter not officially acted upon was the proposed amendment providing for alternate Governors.

After general discussion, the following resolution was moved, seconded and regularly carried:

RESOLVED, that the following paragraph be added at the end of Article IV, Section 1, of the By-Laws, and that notice of the proposed addition to the By-Laws be published in the ANNALS OF INTERNAL MEDICINE at least one month in advance of the next Annual Business Meeting in 1938:

"Any member of the Board of Governors unable to attend the Annual Session shall appoint as his alternate, with all the privileges of a Governor, a Master or Fellow of his district who will be in attendance at that Session. Upon presentation to the Chairman of the Board of Governors of a certificate of appointment, the alternate shall be recognized and act in the full capacity of Governor for the Session to which he has been appointed. The same alternate shall not be appointed for more than two consecutive years."

President Bradley stated that a number of members had suggested the propriety of having a history of the College written to date, while there are still members thoroughly conversant with all the past details since organization. Dr Bradley thereupon appointed Dr William Gerry Morgan to write such a history at his leisure.

On motion by Dr James Alex Miller, seconded by Dr Pepper, and regularly carried, it was

RESOLVED, that the Committee on Nominations take under consideration the nomination of a Governor for the State of South Dakota, since that State now qualifies to have its own Governor

Dr Walter L Bierring, Chairman of the American Board of Internal Medicine, reminded the Board of Regents that each one is an Adviser to his Board. He reported that the Board had in its files 1,030 applications for certification without examination. They had been arranged by states and cities, and the Board desires as much advice from the Regents as possible in the valuation and determination of the eligibility of these applicants. Dr Bierring also referred to refunding to the American College of Physicians, in partial payments in annual allotments, the loan that had been made to the American Board of Internal Medicine.

Dr Pepper suggested no action be taken until the American Board of Internal Medicine had further opportunity of reviewing their finances and determining upon a definite refunding plan.

On motion by Dr Pepper, seconded and regularly carried, it was

RESOLVED, that the sum of \$100.00 be appropriated for the uses of the College Historian, should he find need of extra clerical assistance, or in any other matters connected with preparing the history of the College.

Adjournment

Attest E R LOVELAND,
Secretary

MINUTES OF THE BOARD OF REGENTS

St Louis, Mo

April 20, 1937

The second meeting of the Board of Regents, during the Twenty-first Annual Session, was held at the Jefferson Hotel, St Louis, April 20, 1937, with President Ernest B Bradley presiding and the Executive Secretary acting as secretary of the meeting. On the calling of the roll, the following were recorded as present:

Ernest B Bradley, *President*,
James H Means, *President-Elect*,
O H Perry Pepper, *First Vice-President*,
Walter L Bierring, *Third Vice-President*,
William Gerry Morgan, *Secretary-General*,
William D Stroud, *Treasurer*,
William J Kerr,
Roger I Lee,
Sydney R Miller,
George Morris Piersol,
G Gill Richards,
Robert A Cooke,
James B Herriek,
Hugh J Morgan,
James E Paullin,
Egerton L Crispin,
James Alex Miller,
Francis M Pottenger,
Charles H Coeke,
Maurice C Pineoffs

Upon motion, seconded and regularly carried, the reading of the Minutes of the previous meeting was dispensed with

Chairman Bradley called for the presentation of additional resolutions

Dr William Gerry Morgan, as Secretary-General, presented the following resolution on the death of Dr Henry F Stoll, as prepared by Dr George Blumer, Governor for Connecticut

HENRY FARNUM STOLL

"Whereas The Almighty, in his inscrutable wisdom, has seen fit to remove from our midst our friend and colleague, Henry Farnum Stoll, and

"Whereas In his unstinted devotion to duty, his high appreciation of the importance of the public as well as the private aspects of medical practice, his constant efforts to extend the limits of knowledge in his field, and his vital interest in the welfare of his patients he exemplified the best traditions of the medical profession, therefore,

"BE IT RESOLVED, that we place upon our Minutes a record of our sorrow at his passing and our appreciation of his many admirable qualities, and that we extend to his family our heartfelt sympathy

—GEORGE BLUMER, M D, F A C P "

On motion, seconded and regularly carried, the above resolution was adopted

Dr Morgan then presented the following resolution, prepared by Dr David P Barr, on the death of Dr W McKim Marriott

WILLIAM MCKIM MARRIOTT

"William McKim Marriott, Fellow and former Regent of the American College of Physicians, died on November 11, 1936 He was Professor of Pediatrics and for thirteen years was Dean of the School of Medicine at Washington University As teacher and investigator, he achieved an international reputation As a medical administrator, he saw with clarity the great problems of medical education in a rapidly changing practice Although possessed of a fine critical faculty, he was generous and tolerant of the weaknesses and faults of others To a remarkable degree, he was able to see the point of view of his colleagues, to reconcile conflicting opinions, to clarify issues and to accomplish joint action Above all, he was imbued with a spirit of optimism which enabled him to ride over difficulties, to proceed after defeat and to pursue under most adverse circumstances the ideals to which he was devoted

"Dr Marriott's training had not been that of an administrator He had prepared himself as a chemist, a pediatrician and a teacher It was in these directions that he had progressed during his youth With his numerous executive duties, with the never-ending exactions of the Dean's Office, he was able to continue the work for which he was especially qualified It was during the period of his Deanship that his semi-annual course in pediatrics became one of the most important single factors in the postgraduate training of specialists in diseases of children He served on the editorial board of the American Journal of Diseases of Children He prepared and published lectures on 'Recent Advances in Chemistry in Relation to Medical Practice' He published his classic monograph on 'Infant Nutrition' On the busiest days he was able to make his rounds in the hospital, to supervise the innumerable activities of one of the most productive departments of pediatrics in the world At one time he was an officer in the Southern Medical Association He served effectively on the Council of Pharmacy and Chemistry of the American Medical Association He was active in the formation of the Council on Foods In the midst of all this activity, it was remarkable that he was never too busy to be available to the younger men of his staff, and was never too pre-occupied to offer them inspiration, guidance and help from his great experience From among his pupils, universities have chosen men to fill some of the most important positions in the field of pediatrics

"Dr Marriott possessed one of the great medical minds of our generation In the

breadth of his vision he had few equals. His profundity in diverse fields is attested by his achievements.

"The American College of Physicians was fortunate to have him among those who have made it one of the great medical organizations. It grieves with others in the loss of one of the great leaders in medicine and in the world of science.

—DAVID P. BARR, M.D., F.A.C.P."

On motion, seconded and regularly carried, the above resolution was adopted.

Dr. James E. Paullin, Chairman of the Committee on Public Relations, presented the following report and recommendations:

(1) That the following resignations be accepted:

Dr. Daniel F. Milam (Fellow), Hastings-on-Hudson, N. Y.

Dr. Bernard A. Manace (Associate), Toronto, Ont.

Dr. Vincent D. King (Associate), Memphis, Tenn.

Dr. Edward L. Voke (Associate), Akron, Ohio.

Upon motion by Dr. William Gerry Morgan, duly seconded and carried, it was

RESOLVED, that the resignations of Doctors Milam, Manace, King and Voke be accepted.

(2) The Committee recommended that the resignation of Dr. Frederick H. Lamb (Associate), Davenport, Iowa, be held in abeyance, pending further correspondence with Dr. Walter L. Bierring, in view of the fact that the Governor for Iowa had not furnished sufficient data to enable the Committee to make a recommendation.

Upon motion by Dr. William Gerry Morgan, duly seconded and carried, it was

RESOLVED, that the resignation of Dr. Frederick H. Lamb (Associate), Davenport, Iowa, be held in abeyance, pending further correspondence with Dr. Walter L. Bierring.

(3) The Committee recommended that the dues of Major F. R. Borden (Fellow), M. C., U. S. Army, retired, be remitted because of physical disability.

On motion by Dr. James Alex. Miller, duly seconded and regularly carried, it was

RESOLVED, that the dues of Major F. R. Borden, M. C., U. S. Army, be remitted because of physical disability.

(4) The Committee recommended that the letter of Dr. E. M. Stevenson, of Bloomington, Ill., be returned to the Executive Secretary without comment.

Upon motion, seconded and regularly carried, the entire report of the Committee on Public Relations was adopted.

Dr. James Alex. Miller reported, as Chairman of the Committee on Future Policy for the Development of Internal Medicine, as follows:

"A meeting of the Committee on Future Policy for the Development of Internal Medicine was held on April 19, 1937. There were present Dr. James Alex. Miller, Chairman, Dr. F. M. Pottenger, Dr. Maurice C. Pincoffs, and Dr. Roger I. Lee.

"The various proposals concerning the future policy of the College were considered, and, in general, it was the consensus of opinion that the chief emphasis in future policy should be upon efforts to improve postgraduate education in Internal Medicine in this country, and, particularly, for Fellows and Associates of the College.

"1 The suggestion that the College set up a revolving loan fund to aid candidates for certification by the American Board of Internal Medicine, so that candidates might be enabled to undertake studies which would fit them to meet the requirements of these examinations was recommended as worthy of approval by the Regents if and when the financial resources permit.

"2 The recommendation that the College establish lectureships to be given by outstanding internists, both from foreign countries and the United States, was considered, but the Committee does not deem it wise at the present time at least to recommend this as a policy for the College.

- "3 Dr Herman Mosenthal presented a proposition for the establishment of regular short courses for postgraduate students in Internal Medicine in certain selected medical centers. It was Dr Mosenthal's suggestion that the College consider the appropriation of a sum of money to provide for an executive secretary to organize and administer such courses. This proposition was not approved by the Committee.
- "4 It was brought to the attention of the Committee that a tentative movement is on foot to provide a survey of all postgraduate facilities in the United States and that it had been intimated that funds for conducting such a survey might be available, if the need for it was indicated on the part of representative medical organizations. The Committee voted to recommend to the Regents that they approve a plan for such a national survey of postgraduate facilities as far as it relates to Internal Medicine, provided that the survey was planned and conducted under suitable auspices and provided that as a part of the survey some plan for a continuing organization which would afford opportunities for information and guidance for prospective postgraduate students was proposed.
- "5 The Committee thoroughly discussed the desirability of the College doing something of a specific nature to provide postgraduate courses for its Fellows and Associates. As a result of this discussion, it was specifically recommended that the Board of Regents consider the feasibility of providing special short courses in various branches of Internal Medicine to be held at about the time of each Annual Session. These courses to be organized both in the city where the Session is held and in conveniently located near-by medical centers. It was suggested that such courses might be of two weeks' duration and be conducted either immediately before or immediately after the week of the general Session. It was also recommended that the Regents consider giving some financial assistance to the organization of such courses, so that any fees that were charged could be kept very low. It was specifically suggested that an assistant to Mr Loveland might be provided to take charge of this work.
- "6 The Committee also discussed the policy the College should have in the future toward its commercial exhibits. It is the opinion of the Committee that the character of the commercial exhibits should be kept of a very high order, and that the College should bear in mind that in the future it should not be wholly dependent upon the income from the commercial exhibits so as to in any way influence the character of the exhibits. Toward this end, it was suggested that the Board of Regents might appoint a subcommittee to make a special study of this question.
- "7 The general question of the future policy of the College, as it relates to membership in the various allied specialties and, particularly, as it relates to the policy of the College toward the American Board of Internal Medicine was discussed. It was the sense of the Committee that the action in delaying the proposed changes in the Constitution and By-Laws concerning these questions is wise but the Committee wishes to emphasize to the Board of Regents its strong feeling that the policy of the College should gradually extend toward a raising of standards which eventually might reach the standards set in the proposed amendments, to the end that the standards of practice in Internal Medicine in general may be raised and that Fellowship in the College may be increasingly considered as an honor.

"In connection with the problem of the allied specialties, it was the feeling of this Committee that the retention of a certain number of Fellows representing these specialties would be desirable, but that in the future any applications for Fellowship in this class should be scrutinized with especial care and should ultimately probably require the certification of each candidate by his own special National Board or, lacking that, its equivalent in professional or scientific achievement."

Discussion of the Report

Item four Dr Miller explained that this proposal is simply a matter as to whether the Board of Regents desires to place on its Minutes the approval of the recommendation of

the Committee that there should be considered, under proper safeguards, a survey of post-graduate facilities in Internal Medicine. Dr. Miller said his Committee was unanimously in favor of it, and offered a resolution that the recommendation be adopted. The motion was seconded by Dr. Kerr.

In the discussion of the motion, it was again pointed out that the recommendation could not be made more specific at the present time, because the plan will come back again when it is consummated, but, in order to get the survey started, a few medical organizations would have to say that they think such a survey, properly conducted, would be desirable.

Chairman Bradley inquired about the source of funds for such a survey. Dr. Miller replied that funds might be provided from two of the large foundations, but these foundations would wish to know first whether the American College of Physicians and the New York Academy of Medicine believe such a survey would be useful and desirable.

Dr. Pincoffs suggested that this motion should be sent to the Council on Education of the American Medical Association, so that the College would be dealing at once with them, and with any one else who might be interested in such a survey, showing that the resolution by the College does not designate any foundation, but merely indicates the desirability of such a survey, under proper auspices.

The motion was then put to vote and regularly carried.

RESOLVED, that the American College of Physicians approve in principle that a survey of all postgraduate facilities of the United States would be desirable, so far as it relates to Internal Medicine, providing that the survey be planned and conducted under suitable auspices, and providing that as a part of the survey, some plan be proposed for a continuing organization, which will afford opportunities for information and guidance for prospective postgraduate students.

Discussing recommendation "five" of the Committee, Dr. Miller said:

"This is a very far reaching suggestion looking toward an effort to do something specifically for our College members, and to do it in a way which they would feel in a large part is a contribution open to them because of their Associateship or Fellowship in the College, and an opportunity to extend the College's postgraduate activities. These courses would be open only to Associates and Fellows of the College. It would be determined in advance what courses are available in the city, or near-by cities, where our courses would be conducted. The members of the College would have to be circularized through the 'Annals,' and in every other way. It might add to the prestige of the College, and we hope it would add to the services extended to our membership. We were hoping that the fee charged might be a nominal one, perhaps \$10.00. The proposal involves a consideration of honoraria to those giving the courses, or, perhaps, from the beginning the plan might be tried on an honoraria basis. The plan might involve the appointment of an assistant to the Executive Secretary who would be competent to do some medical work in the College. The courses would naturally be organized by a local group, but could be organized in any manner desired, with the courses being offered not only by Fellows of the College, but by others who might be selected.

"The recommendation before the Regents, first, requires the approval of the principle, and, secondly, requires consideration of ways and means of carrying it out and expenditures therewith involved. If approved, the proposal probably involves the appointment of a special committee. It seems to me that today we might go so far as to approve the principle of giving such services to our Fellows and Associates, by these short courses at about the time of the Annual Sessions. If this proposal should be undertaken next year, and the Annual Meeting should be held in New York City, courses could readily be organized, using the facilities of New York, of Philadelphia, of Boston, and of New Haven, at least for such clinics. There should be no great difficulty in organizing two-week courses in all the various branches of Internal Medicine. I move the approval of the Board of Regents of the project as a desirable activity of the

College, and the appointment of a special sub-committee to be concerned solely with the project"

The motion was seconded by Dr William Gerry Morgan

In the discussion, Dr Miller pointed out that if expenditures should be involved, the Executive Committee of the Board of Regents has power, in the interim, to act on all necessary expenditures

Dr James E Pullin expressed his hearty approval of the proposal, but asked that the Committee might even broaden its scope. There have been springing up all over the country various postgraduate courses. The College might be able to serve a very useful purpose, and instead of limiting its postgraduate activities to just before the Annual Meeting, it could sponsor, conduct and supervise postgraduate courses in the various districts of the country, bringing the courses near at hand to the members, and not requiring so much of their time for the Annual Meetings, often conducted at a long distance removed from their homes

Dr Miller pointed out that in his opinion, for the first year or two, the College might better confine its activities to one set of courses, perfect its method of organization, get more experience, and then probably expand the principles if it works out successfully. Furthermore, by that time, the survey of postgraduate facilities might be completed, and the Committee probably could report back on further procedure

The motion was then put to a vote, and unanimously carried

RESOLVED, that the Board of Regents approve of the feasibility of providing special postgraduate courses in various branches of Internal Medicine to be held at about the time of each Annual Session, these courses to be organized both in the city where the Session is held and in conveniently located, near-by medical centers, further, that the Board of Regents approve the appointment of a special sub-committee to be concerned solely with this project

In further commenting upon the action taken, Dr Pincoffs suggested that the members of the Board and the committee, when appointed, consider the project carefully, so that they will be ready for definite action at the 1937 autumn meeting of the Board of Regents

Dr James Alex Miller pointed out that the committee should bear in mind that there is a definite implication that the fees charged to our members should be kept as low as possible

Dr Miller further said that the medical assistant might find many avenues of service to the College which might materially strengthen the Organization

In discussing item "six" on the report of the Committee concerned with the matter of commercial exhibits and advertising, Dr Miller emphasized the need for a complete study of both exhibits and advertising, with a view to keeping both on the highest possible plane. In regard to exhibits, the suggestion was made that perhaps they could be somewhat more restricted in their extent, with the elimination of any exhibit that is not specifically relevant to the practice of Internal Medicine, or one of its affiliated specialties

Upon motion by Dr James Alex Miller, seconded by Dr William Gerry Morgan, and regularly carried, it was

RESOLVED, that the Committee on Advertising and Commercial Exhibits, as presently constituted, be terminated, and that a new Committee be appointed by the incoming President, the duties of the Committee to make a survey and to formulate future policies for the acceptance of advertisements in the "Annals of Internal Medicine" and the acceptance of exhibits for our Annual Sessions

No action was required on item "seven" of the Committee's report. However, item "one" on the report not previously discussed, was again reviewed, namely, the setting up of a revolving loan fund to aid candidates seeking certification by the American Board of Internal Medicine enabling them to undertake studies which would fit them to meet the requirements of these examinations

Dr Maurice C Pincoffs, speaking on the matter, said "It occurs to me that the College is playing a considerable part in making it harder for men to enter Internal Medicine, and

that we stand in not a little danger of having our internists selected by their financial capacity, rather than by their character and by their brains. The College might well do something to help some of these younger men who may be crowded out of the career of Internal Medicine, though they are well fitted for it in every other way than finances. There are throughout the country a great number of revolving loan funds in connection with undergraduate and, to some extent, graduate work. There is in New York a foundation which itself operates such a fund, and which has made a study of the broader question of revolving loan funds. While we may not be able to take action today, it seems to me a project well worthy of studying, and a committee might be appointed by the President to obtain the assistance of that foundation, which was offered gratis and very willingly, in working out a definite and specific plan on the basis of its experience with revolving loan funds in general among students and graduates; the committee to submit their findings at the autumn meeting of the Board of Regents, so that the matter may be considered in terms of experience, in dollars and cents, in relation to our finances."

On motion by Dr. Pincoffs, seconded by Dr. Kerr, it was

RESOLVED, that the Board of Regents shall appoint a special committee for the purpose of studying the question of the operation of revolving loan funds for medical graduates preparing for certification.

Speaking to the motion Dr. Kerr said in part: "One of the problems confronting us is that a number of younger men who are encouraged, and, perhaps, expected, to spend a year or more in one of the basic sciences or fundamental branches of medicine, after their medical school years may not be able to do so. It, therefore, seems to me if we could provide the means for this in some measure through a loan fund, we would reap the benefits. I was very much impressed by the recommendations of the Committee on Future Policy for the Development of Internal Medicine in other directions, looking toward postgraduate education. I think they are all in the right direction, and it seems to me that the College is now beginning to have some real objectives, objectives that our Governors and Fellows have been looking for us to establish."

The motion was put to a vote and unanimously adopted.

The appointment of the Committee was left to the incoming President.

On motion by Dr. Paullin, duly seconded and carried, it was

RESOLVED, that the Board of Regents adopt the report, as a whole, of the Committee on Future Policy for the Development of Internal Medicine.

Dr. Pincoffs had no specific report as Editor of the ANNALS OF INTERNAL MEDICINE, saying that his report will be covered by the report of the Committee on the ANNALS, which will be given by the Chairman, Dr. Means.

Dr. James H. Means, Chairman of the Committee on the ANNALS, reported that a meeting had been held with all members of the Committee present, and with the Editor, Dr. Stroud and Dr. Pepper present by invitation. The affairs of the ANNALS had been discussed with the Editor, and no specific recommendations were presented. The chief item of consideration had been that of festschriften, particularly a festschrift for Dr. Joseph H. Pratt, of Boston. The Editor's policy in regard to the handling of festschriften was considered further by the Committee.

At this point, Dr. Pincoffs explained that in selected cases where an anniversary volume is to be published in honor of some outstanding medical authority, certain of the articles might be accepted for publication in the ANNALS OF INTERNAL MEDICINE, so that they may have a permanent place in medical literature, the right to be reserved to publish only such of those articles as the Editor might feel meet the standards of the ANNALS. They will be published with a modest heading, explaining that they are to form a part of an anniversary volume. The College, or the ANNALS, will take no part in organizing or sponsoring a festschrift to any one, merely adopting the policy of publishing in the ANNALS, under proper heading, suitable material from such festschrift. The ANNALS may gain considerable valuable material in this manner. The first articles from the festschrift of Dr. Joseph H. Pratt,

of Boston, marking his sixty-fifth birthday, will appear in the May, 1937, issue of the ANNALS, and continue through December. The committee in charge of the festschrift has made its own arrangements with our publishers, so that the type from these articles in the ANNALS can later be used in publishing its volume, to which will probably be added such other festschrift articles as have not been accepted for the ANNALS. Dr. Pineoffs said that it is his belief that this is the first time any medical journal has undertaken this matter, and expressed the hope that it is going to have some merit in adding to the value of festschrifts in the future. So often they are a total loss to medical literature.

Dr. Walter L. Bierring reported that the American Board of Internal Medicine had discussed the method of refunding its financial obligation to the College, and that it had taken action authorizing the refunding to the College at this time \$5,000.00 of its loan and a check for said amount was delivered to the College.

Dr. William D. Stroud, Treasurer, presented the following report:

"To the Board of Regents

"As of March 31, 1937, the College has invested securities of a book value amounting to \$101,857.00, of this amount, \$58,853.00 is in the Endowment Fund and \$43,004.00 is in the General Fund, \$82,250.00, or 80.75% of the above amount is invested in bonds, \$4,741.00, or 4.65% is invested in preferred stocks, and \$14,866.00, or 14.60% is invested in common stocks. In addition, the college has in bank balances \$47,470.00, making a total of \$149,328.00 as compared with a total of \$157,329.00 approximately one year ago at the time of the last yearly meeting.

Respectfully submitted,

(Signed) WILLIAM D. STROUD, *Treasurer*"

He pointed out that in spite of having purchased the new College Headquarters and having paid for the improvements and furnishings, the invested capital of the College was only \$8,000.00 less than a year previous.

Upon motion by Dr. James Alex. Miller, seconded by Dr. William Gerry Morgan, it was RESOLVED, that the report of the Treasurer be accepted and placed on file.

Dr. James Alex. Miller, as Chairman of the Committee on Finance, presented the following report:

"A meeting of the Finance Committee was held on April 19, 1937. There were present Dr. James Alex. Miller in the Chair, Dr. Roger I. Lee and Dr. William D. Stroud.

"The financial statements were submitted by the Treasurer and by the Executive Secretary, and also an analysis of the present investment list by the Investment Counsel. Upon recommendation of the Treasurer and of the Executive Secretary, it was decided that \$15,000.00 might be safely withdrawn from the available cash funds in the General Fund for investment. It was voted to approve the investment of this amount for the General Fund account in securities later to be approved upon the recommendation of the Investment Counsel. Upon recommendation of the Investment Counsel, the sale of \$5,000.00 of Chesapeake and Ohio, 3½s, due 5-1-96 was authorized. This is for the Endowment Fund account. Also, upon the recommendation of the Investment Counsel, it was authorized to sell the following:

50 Shares General Motors Corporation, common
45 Shares Mid-Continent Petroleum Corporation
70 Shares National Breweries, Ltd., common

These three transactions are for the General Fund account.

"Also, it was voted to authorize to buy for the Endowment Fund account \$5,000.00 of Northern States Power Company, First Refunding 3½s, due 2-1-67. It was also voted to buy for the General Fund account, 50 Shares of Chase National Bank of New

York, common stock, and 30 Shares of Pacific Gas and Electric Corporation, 6%, cumulative preferred

"The recommendation of the Investment Counsel to invest the remaining \$3,300.00 realized from the above sales for the General Fund account in U. S. Treasury, 1½%, was not approved, but it was voted to invest this amount, together with the \$20,000.00 above approved for investment for the General Fund account"

In commenting upon the report, Dr. Miller stated that his Committee finds the financial situation of the College most satisfactory. He expressed full satisfaction and appreciation of the value of the services of our Investment Counsel. This Counsel has been of constant aid to the Committee, and in their recent survey commended very highly the character of the College investments.

Upon motion by Dr. James Alex. Miller, seconded by Dr. William Gerry Morgan, it was voted that the report of the Finance Committee be accepted and adopted.

At this point in the program, the Washington, D. C., delegation was admitted, in order that it might present its invitation to the College to hold its 1939 Annual Session in Washington.

An invitation to meet in Washington, D. C., in 1939 was extended by Dr. William Gerry Morgan, Secretary-General, by Dr. Wallace M. Yater, Governor for the District of Columbia, by Dr. Thomas Parran, Surgeon General of the U. S. Public Health Service, by Admiral Percival S. Rossiter, Surgeon General of the U. S. Navy and by Dr. Robert U. Patterson, former Surgeon General of the U. S. Army.

DR. CHARLES H. COCKE, Chairman of the Board of Governors: "The Board of Governors, being deeply sensible of, and deeply grateful for the hospitality of the Regents during recent years, instructed me to invite you to be their guest at the next Annual Meeting, on the Sunday evening preceeding the opening of the Session."

Dr. Cocke further reported that there had been the largest attendance by members of the Board of Governors in the history of the College.

President Bradley expressed the thanks of the Regents for the invitation from the Governors, and accepted the invitation on behalf of the Regents.

President Bradley then reported that there had been a special committee, consisting of the President, President-Elect and the First Vice President, appointed during December, 1936, to confer with a committee from the American College of Surgeons on general subjects. Such a meeting was held at St. Louis with Dr. George Crile and Dr. Irvin Abell, representing the American College of Surgeons, Dr. Crile being Chairman of their Board of Regents, and Dr. Abell being the Secretary. Out of the meeting grew no definite recommendations to be made to the Board of Regents of the American College of Physicians. Dr. Bradley, however, recommended that a like committee be appointed during the coming year to continue these conferences.

Dr. Bradley thereupon called upon Dr. Maurice C. Pincoffs to read the statement concerning the withdrawal of the amendments to the Constitution and By-Laws, as authorized at the preceding meeting of the Board of Regents, which Dr. Pincoffs presented as follows:

"It is the feeling of the Regents that the standards for admission to the College should be progressively raised. A change in the By-Laws, making certification by the American Board of Internal Medicine a prerequisite to Associateship, was considered in recent months by the Regents. It was felt, however, that this would at this time constitute too radical an increase in the requirements, and so this proposed amendment has been withdrawn. After further consideration, other proposals for increasing the standards will be submitted to the College.

"Another amendment discontinuing the admission to the College of physicians working in fields allied to Internal Medicine has likewise been withdrawn by the Regents. It is the present feeling of the Regents that the admission of a certain number of Fellows representing these specialties would be desirable. Any application for Fellowship

in this class should be scrutinized with especial care, and should ultimately probably require the certification of each candidate by his own special certifying Board, or, lacking that, its equivalent in professional or scientific achievement."

Upon motion by Dr James Alex Miller, seconded by Dr Walter L Bierring, and regularly carried, it was

RESOLVED, that the Board of Regents approve of the above statement

Dr Charles H Cocke, is Chairman of the Board of Governors, again inquired about the matter of alternate Governors. He reported that alternate Governors had been seated at the present meetings by agreement within the Board of Governors.

President Bradley said that he felt there would be no objection to this action until the particular amendment to the By-Laws has been officially adopted.

The Executive Secretary then presented a report on the Associates who were elected at the 1932 Annual Session. The following analysis was presented:

| | |
|--------------------------------------|-------|
| Qualified for Fellowship | 70 |
| Deceased | 3 |
| Resigned | 2 |
| Failed to take up election | 1 |
| Dropped | 9 |
| | <hr/> |
| Total candidates elected '32 Session | 85 |

Nine Associates elected at the 1932 Session were automatically dropped for failure to present the requisite credentials for Fellowship within the five-year maximum period, as provided by the By-Laws.

Six Fellows and 5 Associates were by resolution discontinued on the Roster of the College because of delinquency of more than two years' standing.

The Executive Secretary then presented to members of the Board of Regents copies of the pamphlet in which all gifts to the College Library have been recorded, the pamphlet being an index to the College Library of publications by members. A sufficient quantity of these indices have been printed, and were being given to all members interested at this Session.

Mr Loveland then called to the attention of the Board of Regents that a new Directory of the College would be published during the coming summer. He asked for directions in two respects: (1) whether it is the wish of the Board of Regents that the Directory continue to carry the names of Associates, as well as Masters and Fellows, (2) he suggested the appointment of a consulting committee to consider what specialty listings would be approved for record in the Directory.

In the discussion that ensued, it was the consensus of opinion that the Associates should continue to be listed in the Directory, and that a plan should be worked out by which those consulting the Directory would not likely confuse Associates with Fellows.

On motion by Dr James Alex Miller, seconded by Dr Walter L Bierring, and regularly carried, it was

RESOLVED, that there shall be appointed a committee of three to act in a consulting capacity in regard to the publication of the new Directory, this committee being delegated power to decide on the manner of listing Associates, and the list of sub-specialties to be recognized.

Adjournment

Attest E R LOVELAND,
Executive Secretary

MINUTES OF THE BOARD OF REGENTS

St Louis, Mo

April 23, 1937

The final meeting of the Board of Regents, during the Twenty-first Annual Session, was held at the Jefferson Hotel, St Louis, April 23, 1937, with President James H Means presiding, Mr E R Loveland acting as secretary, and with the following Regents present

James H Means, *President*,
 William J Kerr, *President-Elect*,
 David P Barr, *First Vice-President*,
 G Gill Richards, *Second Vice-President*,
 William Gerry Morgan, *Third Vice-President*,
 William D Stroud, *Treasurer*,
 Ernest B Bradley,
 O H Perry Pepper,
 Walter L Biering,
 Hugh J Morgan
 James E Paulin,
 Egerton L Crispin,
 James Alex Miller,
 Francis M Pottenger,
 Charles H Coeke,
 Maurice C Pineofts

Upon motion duly seconded and carried, it was RESOLVED to dispense with the reading of the Minutes of the preceding meeting of the Board of Regents

The Chairman recognized Dr John H Musser, of New Orleans, who presented an urgent invitation for the College to hold its 1939 Annual Session in New Orleans

The Chairman also recognized Dr William J Kerr, of San Francisco, who presented a like invitation for the College to hold its 1939 Annual Session in San Francisco

Dr Bradley reported that some of the Cincinnati Fellows of the College had expressed to him the desire to extend an invitation to the College to meet in Cincinnati Dr Bradley stated that he was herewith presenting the invitation from Cincinnati, to consider that City some year in the future He reviewed the general and clinical facilities of Cincinnati for holding the meeting

At this point, the secretary, Mr Loveland, was asked to read the invitation of the City of Cleveland, in the absence of Dr Willard C Stoner, who had been unable to remain for this meeting

Mr Loveland presented the invitation prepared by Dr Stoner for the College to select Cleveland for its 1939 Annual Session He also reported that he had before him telegrams from the Mayor of Cleveland, from the Convention Bureau, from the Dean of Western Reserve University School of Medicine and from the Academy of Medicine of Cleveland, all urging the acceptance of Cleveland for the 1939 Session

Mr Loveland also reported that there was still outstanding an invitation from Memphis for one of the Annual Sessions of the College

The Chairman, Dr Means, then recognized Dr James Alex Miller

DR JAMES ALEX MILLER "I may say that since the last meeting of the Board of Regents, when New York's invitation was first suggested, or offered we have had an expression of medical interest in the College on behalf of very outstanding members of the Medical Profession, and from inquiries which some of us have made, there is no doubt whatever that if we decide to come to New York next year, you are going to have 100 per cent cooperation from all the large medical centers

"Also, from preliminary surveys of the opportunities that will be offered from the standpoint of hotel accommodations, accommodations for the clinical staff, for the round tables, for the exhibits, and all of that part which has to do with the executive side of the Session, it seems as though if we do decide to come to New York next year, and we decide fairly soon, we will be able to get what we consider ideal accommodations.

"So that, on behalf of the Officers of the College, resident in New York, and also on behalf of a large number of others, including the Mayor and others who are interested in New York as a convention center, whose communications I will not take the trouble to read to you, we can offer you a very hearty invitation, and I think we can promise to put on a very good meeting for the College at that time."

At this point, the Chairman recognized Dr M A Shillington, of St Paul, who presented an invitation to the College to select St Paul for its 1939 Annual Session. Dr Shillington discussed in detail the facilities of St Paul and the advantages of holding an Annual Session of the College in that City.

Dr Charles H Cocke, Chairman of the Board of Governors, was called upon for a report of that Board. He stated that at the second meeting of his Board, thirty-nine members had been present, and that they had received the report from the Board of Regents with interest and earnest consideration. The Board of Governors wished to recommend to the Consulting Committee on the Directory that the Associates be listed in the Directory, but in the geographical index be designated as "Associates" and listed immediately under the same States and cities as the Fellows.

The Board of Governors had voted unanimously to recommend to the Committee on Postgraduate Study, through the Board of Regents, that the courses be developed as soon as practicable, and that they should be of a minimum of not less than two, or of a maximum of not more than four weeks' duration.

The Board of Governors also had voted unanimously to recommend to the Board of Regents that the "allied specialties" be retained in the Constitution.

On motion duly seconded and regularly carried, it was

RESOLVED that the report from the Board of Governors be received and recorded.

At this point, the order of business called for the election of the Treasurer and Secretary-General for 1937-38.

On motion by Dr Paullin, seconded by Dr Richards, and unanimously carried, Dr William D Stroud was nominated for reelection as Treasurer. As there were no other nominations, Dr Stroud was declared elected.

Dr William Gerry Morgan "Mr President, I wish to put in a nomination, but before doing so, I want to take this opportunity to express my profound and heartfelt appreciation for the honor extended to me and the courtesies which I have received during my incumbency. My experience during these four years has shown me that it would be very much to the advantage of the College to have a Secretary-General in Philadelphia. There is such a constant exchange of material and matters between the Executive Secretary and the Secretary-General that it would facilitate the carrying on of these business affairs, and it would be a saving to the College from the point of postage and otherwise. Therefore, I take the very greatest pleasure in nominating Dr George Morris Piersol as Secretary-General."

The nomination of Dr Piersol was seconded by Dr Bradley. There were no other nominations and Dr George Morris Piersol was unanimously elected Secretary-General.

The Chairman recognized Dr S Marx White, who entered at this time to second the invitation for the College to select St Paul for its 1939 Session.

President Means then called for the election of an Executive Committee for 1937-38, reading the provisions in the By-Laws governing the same. The President, the President-elect, the Secretary-General and the Treasurer are members of the Executive Committee ex officio. The five additional members formally elected were as follows:

Walter L. Bierring, Des Moines
 Roger I. Lee, Boston
 James Alex. Miller, New York
 Hugh J. Morgan, Nashville
 Maurice C. Pincoffs, Baltimore

President Means then proceeded to the matter of the appointment of committees, reading the personnel of standing committees, the regulations governing same and the names of those whose terms have expired.

The following appointments were made:

COMMITTEE ON ADVERTISEMENTS AND COMMERCIAL EXHIBITS

George Morris Piersol, Chairman, Philadelphia
 William D. Stroud, Philadelphia
 William Gerry Morgan, Washington

COMMITTEE ON THE ANNALS OF INTERNAL MEDICINE

Walter W. Palmer, New York (term expiring 1940)—taking the place of Dr. Egerton L. Crispin, whose term expired. Dr. Means relinquished the Chairmanship and appointed Dr. David P. Barr, already a member of the Committee, to act as Chairman.

COMMITTEE ON FELLOWSHIPS AND AWARDS

James D. Bruce and Egerton L. Crispin appointed in the place of James H. Means and William J. Kerr.

CONSULTING COMMITTEE ON ANNUAL SESSIONS

Appointments automatic—the Committee for 1937–38 shall consist of

James H. Means, Boston, *Chairman*
 James Alex. Miller, New York
 David P. Barr, St. Louis
 Ernest B. Bradley, Lexington

COMMITTEE ON CONSTITUTION AND BY-LAWS

Alfred Stengel (term expiring 1940), reappointed to succeed himself.

COMMITTEE ON CREDENTIALS

George Morris Piersol (term expiring 1940), reappointed to succeed himself from the Board of Regents.

Ernest B. Bradley (term expiring 1938), to fill out the unexpired term of the late Dr. Luther F. Warren.

Dr. Cocke reported that he had reappointed from the Board of Governors, Dr. William B. Breed (term expiring 1940).

COMMITTEE ON FINANCE

Roger I. Lee (term expiring 1940), reappointed to succeed himself.

COMMITTEE ON NOMINATIONS

(President Means announced that he would make his appointments to this Committee in accordance with the By-Laws, within thirty days.)

MINUTES OF THE BOARD OF REGENTS

COMMITTEE ON PUBLIC RELATIONS

Walter L. Biering (term expiring 1941), reappointed to succeed himself
(James H. Means, as President, becomes a member of this Committee, ex officio, succeeding Ernest B. Bradley)

AMERICAN BOARD OF INTERNAL MEDICINE

Representatives appointed by the American College of Physicians included the reappointment of Jonathan C. Meakins (term expiring 1940), and the reappointment of G. Gill Richards (term expiring 1940)

HOUSE COMMITTEE

(The House Committee, consisting of O. H. Perry Pepper, William D. Stroud and James Alex. Miller, had already been reappointed by the Board of Regents at an earlier meeting)

COMMITTEE ON FUTURE POLICY FOR THE DEVELOPMENT OF INTERNAL MEDICINE

(The entire Committee listed below was reappointed)

James Alex. Miller, New York, *Chairman*
Walter L. Biering, Des Moines
Roger I. Lee, Boston
Maurice C. Pincoffs, Baltimore
Francis M. Pottenger, Monrovia

COMMITTEE ON POSTGRADUATE SURVEY

William J. Kerr, San Francisco *Chairman*
Charles H. Cocke, Asheville
Hugh J. Morgan, Nashville

COMMITTEE ON REVOLVING LOAN FUND

Maurice C. Pincoffs, Baltimore, *Chairman*
Roger I. Lee, Boston
Francis M. Pottenger, Monrovia

Upon motion by Dr. W. D. Stroud, seconded by Dr. F. M. Pottenger, and unanimously carried, it was

RESOLVED, that the 1938 Annual Session of the College be held in New York City

Upon motion by Dr. G. Gill Richards, seconded by Dr. Walter L. Biering, and unanimously adopted, it was

RESOLVED, that Dr. James Alex. Miller be appointed General Chairman of the 1938 Annual Session

In responding, Dr. Miller expressed his appreciation both for the selection of New York City and for the confidence expressed in his ability by his appointment as General Chairman. He said everything possible would be done to make the meeting successful. Dr. Miller discussed the matter of the date of the meeting and asked for advice and counsel in all matters from the Board of Regents. He stated that he and the Executive Secretary had already been looking into the facilities of the various hotels in New York, and that they would proceed in accordance with instructions from the Board to designate the headquarters and to select an open date. The opinion had been expressed that a meeting early in March would not be particularly popular, because it breaks up the continuity of winter work for a good many fellows and, perhaps, breaks into the curriculum of the undergraduate teaching in the medical centers. He particularly suggested the week beginning April 3 and the week beginning May 10, as possible appropriate times for the meeting.

Dr James Alex Miller, Chairman of the Finance Committee, expressed the appreciation of the Board for the extraordinary services that the Executive Staff of the College performed, with the large amount of work and extra time devoted to the work by the Executive Secretary and his staff.

On motion by Dr Richards, seconded by Dr Crispin, and regularly carried, it was

RESOLVED, that the Finance Committee shall take under advisement increases in salary for the Executive Staff, with power to act.

Dr Ernest B Bradley, retiring President at this point took the opportunity to thank the members of the Board of Regents for their cooperation with him during his term as President. He recommended that in the future the President should not have charge of the Morning Lectures and Round Tables, but rather that these should be assigned to the General Chairman because the General Chairman in arranging his Clinics should arrange the entire morning program. He expressed the opinion that both of these additions to the program were well justified, as indicated by the large attendance daily. The Morning Lectures were attended by groups numbering from two hundred to four hundred, and the Round Tables turned out to be exceedingly popular.

Dr James Alex Miller pointed out that in his opinion, it is impossible to make up a program of Morning Lectures independent of the General Sessions. There must be close cooperation between the two, he said, and he recommended that possibly the President and the General Chairman might divide the responsibility jointly.

Dr Bradley pointed out that he and the General Chairman, Dr Barr, had consulted frequently, and had worked out all the program more or less, together. Dr Bradley also pointed out that those who had participated in the last two Annual Sessions are members of the Consulting Committee on Annual Sessions and are available to help at all times the President and General Chairman.

President James H Means forwarded the suggestion that the President take charge of the Morning Lectures, so that they may harmonize with the General Sessions, and that the Chairman take charge of the program of Round Tables.

There was general discussion among the members of the Board concerning the propriety of conducting a program of Morning Lectures, some feeling that such a program is unnecessary and that it may conflict with the attendance at the Clinics.

Dr Bradley pointed out that the entire St. Louis program was worked out around the suggestions of the requests of the members. There are those who prefer to attend Clinics, others who prefer the practical Morning Lectures, and a great host who asked for the addition of the Round Tables. He emphasized the importance of giving the members of the College at large what they personally want on the program, rather than dictating what they should have.

Dr Barr disclosed that he had not been in favor of the Morning Lectures, because he felt that they would greatly interfere with his program of Clinics. However, as the meeting turned out, the Morning Lectures were a great advantage in view of the fact that the meeting had been so much larger than expected, that had it not been for the Morning Lectures to take care of overflows, the Clinics would have been swamped. He expressed the opinion that the Morning Lectures might be highly appropriate in the smaller cities where clinical facilities are limited, but that the program might be abbreviated in larger cities where there are unlimited clinical facilities.

Dr Bradley referred to an editorial written by the late Dr Aldred Scott Warthin, some years ago, in which he recommended that at least one session be devoted to the discussion of general questions. He recommended that this might be considered by the program committee for the following year.

Dr William J Kerr decried the tendency of morning clinics developing into lectures, rather than into practical demonstrations, with the showing of patients. The members at large do not want just an additional set of lectures given as clinics, but they desire real clinics with the demonstration of patients and the discussion of cases. Several endorsed the opin-

ions expressed by Dr Kair and emphasized the importance of arranging programs of real clinics at future meetings. Some expressed the opinion that the St. Louis clinics had been an improvement in this respect over the clinic programs given in some other cities.

Dr James Alex. Miller inquired whether those who attend the Morning Lectures are merely the indolent ones who do not get up in time to reach the clinics, and, if such were the case, whether the Morning Lectures should not be delayed until ten-thirty in the morning, and only give a course for an hour or an hour and a half.

Dr Bradley pointed out that in his opinion men went to the Morning Lectures because they were interested in them, and not because they didn't get up in time to go to the Clinics.

Dr Barr reported that the Clinics, especially at the Barnes Hospital, had been largely oversubscribed, and that as many as two hundred had been turned away from some Clinics because of lack of room to accommodate them. An attempt had been made to engage door-men so that those who had reserved tickets would be assured of admission.

Someone pointed out the necessity of scheduling the Round Tables at the New York Session at such time that those attending the Clinics would be able to get back to the Round Tables on time, so that those attending the Round Tables would not be disturbed by attendants coming in continuously throughout the hour.

Dr Richards pointed out that the most distinguishing feature in the Annual Sessions of the American College of Physicians is the program of clinics. He recommended that where possible clinics should be provided for in such quantities as to accommodate every one who desires to attend.

There was some discussion about holding some of the Round Tables at the medical centers where clinics would be conducted in New York. Dr Miller said that this very likely could be arranged at the Presbyterian Hospital, but that other centers would be sufficiently close to the headquarters to make it possible for attendants to return in time for the Round Tables. He further referred to the very excellent facilities at the Waldorf-Astoria Hotel for many Round Tables, with the additional facilities for luncheons.

Dr Barr recommended that there be a gap of a half hour for transportation between the end of the Clinic program and the beginning of the Round Table program. This had not been so arranged at St. Louis with the result that there had been much difficulty in the attendants getting back for the Round Tables.

Prevent Fall Hay Fever with NATIONAL RAGWEED ANTIGEN

National Ragweed Antigen is standardized in nitrogen units, thus affording dependable potency and facilitating minimum bulk doses measured according to the need of the individual patient. Fixed,

or set, doses can not give the selectivity of dose required.

Complete Treatment (24 doses) in Three 5 cc ampul-vials

V 209 { Series "AA" 125 nitrogen units (8 doses) } Three 5 cc
 { Series "A" 250 nitrogen units (8 doses) } ampul-vials
 { Series "B" 500 nitrogen units (8 doses) } \$8 50

Special Ragweed Antigen complete outfit for diagnosis and treatment of Fall Hay Fever, \$10 00. Contains two diagnostic tests for mixed grasses and giant and dwarf ragweeds, 1 ampul-vial each Series

"AA," "A" and "B" Ragweed Antigen, 25 cc ampul-vial Sterile Salt Solution for dilution of Antigen if needed, 25 cc ampul-vial Epinephrine 1-1000 to control local or systemic reactions

RELIEF in a few hours COMPLETE TERMINATION OF ATTACK *May Be Expected From the Use of* POISON IVY ANTIGEN

Relief in a few hours and complete termination of attack in a few days may be expected from the use of Rhus Tox Antigen for poison ivy, Rhus Venenata Antigen for poison oak. These specific antigens are prepared for dermatitis resulting from Rhus Toxicodendron (poison ivy) or Rhus Venenata (poison oak).

The treatment of rhus dermatitis was entirely symptomatic and most unsatisfactory until the active antigens were produced for specific treatment.

The antigens are prepared by The Mulford Colloid Laboratories under U S Gov License 102, and are accepted by the Council on Phar and Chem of the A M A. Poison Ivy Antigens are marketed in an aqueous-alcoholic menstruum and retain their potency for years. They are free from oil and are quickly absorbed. Injections are not likely to produce nodules or tumefactions. Furnished in packages containing four 1 cc ampul-vials, \$3 50. Two 1 cc syringes, \$2 25. One 1 cc syringe, \$1 25.

The ANNALS OF INTERNAL MEDICINE

For Usefulness Through Succeeding Years

Permanent Binder, \$1 25 each—two binders required for a full Volume of twelve issues

A handsome stamped imitation leather binder in two books, each of the right size to hold six issues of the "Annals of Internal Medicine"

A convenient binder in which the journals may be inserted Outside of binder stamped in gold with name of the journal and index to volume and numbers

When ordering be sure to specify Volume and the period for which the binders are to be used

Volume File, \$1 00 each

One of these Volume Files will keep a complete Volume of twelve issues of the "Annals of Internal Medicine" always assembled and readily accessible for reference Indexed on front with name and volume number

While binders are more permanent and more attractive, the Volume File answers the demand for an inexpensive method of preserving the journal

THE AMERICAN COLLEGE OF PHYSICIANS

Philadelphia, Pa.

One thing the patient needs is *Sleep*

WHETHER insomnia is due to worry, nervousness, illness or fear of operative procedure, sleep is essential to restore the physical resources of the body. In many cases, sedatives and hypnotics may be used to advantage.

It is the opinion of authorities who have studied the use of sedatives and hypnotics that the product should be readily soluble to provide prompt, satisfactory therapeutic effect and that elimination should be sufficiently rapid to prevent unduly prolonged or cumulative effects. Ipral Calcium (calcium ethylisopropylbarbiturate) meets these requirements.

Ipral Calcium has been used for over 12 years as a safe sedative and hypnotic. In the usual therapeutic doses no untoward organic or systemic effects have been reported. Undesirable cumulative effect may be

avoided by proper regulation of the dosage. Ipral Calcium is supplied in 2-gr tablets and in powder form for use as a sedative and hypnotic.

Ipral Sodium (sodium ethylisopropylbarbiturate) is supplied in 2-gr capsules for hypnotic use and in 4-gr tablets for pre-anesthetic medication.

Tablets Ipral-Aminopyrine (2 gr Ipral, 2 33 gr Aminopyrine Squibb) provide both analgesic and sedative effects.

Ipral Calcium (Powder) is available in 1-oz bottles. Tablets Ipral Calcium 2 gr, Tablets Ipral-Aminopyrine 4 33 gr, Tablets Ipral Sodium 4 gr and Capsules Ipral Sodium 2 gr are available in bottles of 100 and 1000.

Affords the facilities for modern diagnosis and treatment under unexcelled climatic conditions. Appointments the acme of attractiveness, comfort and convenience. High-class and seasoned Medical Staff. Accepts for diagnosis and treatment practically all disease conditions except mental and nervous diseases requiring specialized environment and care. Highly efficient out-patient department, serving both ambulant patients and those confined to outside places of residence.

Especially recommended for nontuberculous pulmonary conditions, asthma, sinusitis, chronic and acute arthritis, moderate hypertension, etc.

Tuberculosis patients (all forms) accepted as in-patients (special quarters) as well as out-patients.

Special department for various types of physiotherapy (warmed pools, etc.) with experienced graduate physiotherapists in charge and under medical direction. Graduate dietitians directing all dietaries. Facilities for operative surgery, as necessary, orthopedic adjustments, laryngology, ophthalmology, dental surgery, etc. Department of roentgenology (no therapy) under full-time roentgenologist (physician). Unusually well-equipped clinical laboratories.

Fellowship Insignia for Academic Gown

The insignia for academic dress was adopted after exhaustive investigation by a special committee on insignia of the College. It consists of a cross of the shape of the Fellowship Key, exact size as illustrated, of green velvet with the Seal of the College outlined in solid gold braid, to be worn at the option of the Fellow on the right sleeve of the academic gown, about three inches below the shoulder seam. These insignia are made up on order ready to be stitched to the gown.

Price, delivered, \$4.00

ANNALS OF INTERNAL MEDICINE

OFFICIAL PERIODICAL OF THE AMERICAN COLLEGE OF PHYSICIANS

Place of Publication—Prince and Lemon Sts, Lancaster, Pa

Editorial Office—University Hospital,
Baltimore, Md

Executive Office—4200 Pine Street,
Philadelphia, Pa

THE ANNALS OF INTERNAL MEDICINE is published by the American College of Physi-

The contents consist of contributions in the field of internal medicine, editorials, book reviews, and a section devoted to the affairs of the College

MANUSCRIPTS All correspondence relating to the publication of papers and all book monographs for review should be addressed to the editor. No manuscripts will be accepted without his consideration. Bibliographic references are to conform to the following

DOE, J. E. What I know about it, Jr. Am Med Assoc, 1931, xcvi, 2006-2008

Six illustrations per article are allowed without cost to the author. Beyond this number the author must pay the actual cost of illustrations

REPRINTS For each article published, there will be furnished gratis fifty reprints out covers. An order slip for additional reprints, with a table showing cost, will be sent with galley proof to each contributor. If additional reprints over the first fifty are ordered the order slip must be returned to the printer at the time corrected galley proofs are sent to the Editor.

REVIEWS The ANNALS will make an especial feature of the reviews of monographs and bearing upon the field of internal medicine. Authors and publishers wishing to submit such material should send it to the editor. While obviously impossible to make extended reviews of all material, an acknowledgment of all books and monographs sent will be made in the department of reviews

SUBSCRIPTION This periodical is issued monthly, new volumes beginning with the July number each year. Subscriptions may be by the volume or year, but the volume basis is especially recommended. Volumes will consist of approximately 1,400 pages. Subscription price per volume, or per annum, net postpaid \$7.00, United States, Canada, Mexico, Cuba, Canal Zone, Hawaii, Porto Rico, \$7.50, other countries. Prices for back volumes or numbers furnished upon application. Single numbers, current volume, when available, \$1.00. Members of the American College of Physicians receive the ANNALS OF INTERNAL MEDICINE as a part of their membership. Checks should be drawn to the order of W. D. STROUD, M.D., Treasurer, and remitted through the Publication Office or the Executive Secretary's Office.

BUSINESS CORRESPONDENCE All correspondence relating to business matters, advertising, subscriptions to the ANNALS, inquiries concerning membership in the American College of Physicians, et cetera, should be addressed to the Publication Office or to the Executive Secretary. Books and reprints presented to the College Library should be addressed to the Executive Secretary.

Continued on Inside Back Cover Page

About half of all children suffer some form of urologic disease or disturbance before they reach puberty—many of these diseases are needlessly fatal—

PEDIATRIC UROLOGY

By

MEREDITH F CAMPBELL,
MS, MD, FACS

*Professor of Urology, New York University College of
Medicine, Attending Urologist, Bellevue
Hospital, etc*

THIS book presents in a thorough manner the diseases of the urinary and genital tracts in the young. Until publication of this volume there has been no book in any language comparably covering this broad field which in recent years has become one of rapidly increasing importance and interest. In order to give pediatricists and other non-urologists a clear understanding of urographic diagnosis, practically every pyelogram has a schematic line drawing insert to indicate the local pathology and diagnostic criteria. Over 100 pages are devoted to diagnostic procedure, over 200 to the anomalies of the urogenital tract. All phases are taken up in detail, covering both the medical and surgical aspects of urogenital disease in the young.

Etiology, pathology, the clinical picture, and diagnosis are thoroughly covered. Pathology has been considered from the findings in many hundred infants and children, subjected to complete urologic study, which are summarized or tabulated and arranged to amplify the presentation of the various topics. In the consideration of each clinical condition, particular emphasis has been placed on Treatment—the what, when and how.

With the aid of these volumes the non-urologist will be enabled to determine when a child requires urologic investigation or treatment. All technical procedures are carefully detailed.

Last Minute Hay Fever Relief

For the hay fever patient who postpones treatment until the onset of symptoms, prescribe 'Benzedrine Inhaler'

It provides prompt symptomatic relief, and may be carried in the pocket ready for instant use at any time or place

BENZEDRINE INHALER

A VOLATILE VASOCONSTRICTOR

SMITH, KLINE & FRENCH LABORATORIES
PHILADELPHIA, PA
 ESTABLISHED 1841

Each tube is packed with benzylmethylcarbinamine, S K F 0.325 gm oil of lavender 0.097 gm and menthol 0.032 gm. Benzedrine is the registered trade mark for S K F's nasal inhaler and for their brand of the substance whose descriptive name is benzylmethylcarbinamine.

 When a liquid vasoconstrictor is indicated — Prescribe BENZEDRINE SOLUTION

IN cardiac conditions, Aminophylline is recognized as a useful diuretic and myocardial stimulant. It has frequently been employed for the relief of pain and as an adjunct to medication with digitalis.

Aminophylline offers the advantage in comparison with the older xanthine derivatives of greater solubility. It is about 25 times as soluble as theophylline alone.

Aminophylline Squibb (Theophylline with Ethylene Diamine U S P XI) is supplied in tablets of 100 mgm ($1\frac{1}{2}$ gr) and also in crystalline form for prescription use. Tablets Aminophylline Squibb are supplied in bottles of 10 and 100—Aminophylline Squibb in 10-Gm vials and 1-oz bottles.

TRADE **CEBIONE** MARK
CEVITAMIC ACID MERCK

A daily intake of 10 milligrams of vitamin C, which is the practical equivalent of 20 cc of fresh orange or lemon juice, is considered the minimum antiscorbutic daily requirement for a normal infant.

In the presence of infection, the vitamin C requirement is increased.

A partial undetected vitamin C deficiency in the diet may produce such ominous signs or symptoms as pains in the extremities, retarded

growth, faulty dentition, anemia, or hemorrhagic tendencies.

Although most diets contain a sufficient quantity of vitamin C for infants, a supplementary dose of 10 milligrams of Cebione daily would be an added precaution.

Cebione is supplied in 10 milligram tablets—tubes of 10 and bottles of 100—available from your druggist.

A Helpful Vehicle in Diabetic Diets

KNOX GELATINE (U.S.P.)

Diabetic diets can be lifted out of their monotonous rut with the aid of Knox Gelatine (U.S.P.) Forbidden foods are not missed so readily when a diabetic patient receives a varied diet containing tasty, pleasing, gelatinized salads and desserts

Knox Gelatine is 85% protein, making it a simple task to compute any gelatinized dishes. As Knox Gelatine contains no sugar or flavoring, when planning a diet do not confuse it with a ready-prepared jelly powder. Specify Knox Gelatine and be certain.

KNOX GELATINE . . .

is scientifically made from selected long, hard, shank beef-bones — surpasses minimum USP requirements — contains no carbohydrates — fat content less than 0.1% — odorless — tasteless — bacteriologically safe

Send the coupon below to receive helpful, informative literature and more fine recipes such as given below

TOMATO JELLY WITH VEGETABLES (Six Servings)

| | Grams | Prot | Fat | Carb | Cal |
|-------------------------------|-------|------|-----|------|-----|
| 1/2 cup hot water | | | | | |
| 1/2 teasp salt | | | | | |
| 1/2 teasp whole mixed spices | | | | | |
| 1 env Knox Sparkling Gelatine | 7 | 6 | | | |
| 3/4 cup cold water | | | | | |
| 3/4 cup tomatoes strained | 150 | 2 | | 6 | |
| 2 tablespoonfuls vinegar | | | | | |
| 1/2 cup chopped cabbage | 50 | 1 | | 3 | |
| 1/2 cup chopped celery | 60 | 1 | | 2 | |
| 1/4 cup canned green peas | 40 | 1 | | 4 | |
| 1/4 cup cooked carrots cubed | 40 | | | 4 | |

City State

THE tremendous publicity campaign instituted by government agencies to control venereal disease will undoubtedly cause many persons with syphilis to seek treatment. The fight has just begun and much depends upon the effectiveness of the products used.

In this country, authorities agree that maximum curative effects are obtained when an arsenical and a heavy metal are used alternately and continuously for a period of from twelve to eighteen months. For this purpose, two Squibb products are recommended—Neoarsphenamine and Iodobismutol with Saligenin.

Neoarsphenamine Squibb is subjected to exacting control to assure a high margin of safety, uniform strength, ready solubility and high spirocheticidal

activity. Two other Squibb Arsenicals—Arsphenamine and Sulpharsphenamine—are likewise designed to produce maximum therapeutic benefit.

Iodobismutol with Saligenin provides all the systemic effects of bismuth in the treatment of syphilis. It presents bismuth largely in anionic (electro-negative) form. It is rapidly and completely absorbed and slowly excreted, thus providing a relatively prolonged bismuth effect. Repeated injections are well tolerated in both the early and late stages.

Iodobismutol with Saligenin is a propylene glycol solution containing 6 per cent sodium iodobismuthite, 12 per cent sodium iodide and 4 per cent saligenin (a local anesthetic).

MANUFACTURING CHEMISTS TO THE MEDICAL PROFESSION SINCE 1858

EDUCATION

Education is more than classroom exercise. In a broad sense, it is the development of all those natural faculties which dominate physical and mental character. Where physical education has been neglected as in the instance of constipation, wise counsel and selected treatment often expedite the return to normal function. As an adjunct to the treatment of diet and exercise, Petrolagar is

a useful and convenient method of correcting constipation. By its bland lubricating action, Petrolagar produces soft well formed stools which are easy to evacuate. Petrolagar is prepared in five types—Plain, with Phenolphthalein, with Milk of Magnesia, Unsweetened and with Cascara—to provide a range of treatment adaptable to the individual patient. Petrolagar Laboratories, Inc., Chicago, Ill.

Petrolagar is a mechanical emulsion of pure liquid petrolatum (65% by volume) and agar agar. Accepted by the Council on Pharmacy and Chemistry of the American Medical Association for the treatment of constipation.

Petrolagar

PROTAMINE, ZINC & ILETIN (INSULIN, LILLY)

PROTAMINE ZINC INSULIN LILLY

● Preparation of the active antidiabetic principle in sparingly soluble form as Protamine Zinc Insulin provides a means for prolonging the relatively fleeting action of unmodified Insulin. The characteristic antidiabetic effect of Insulin has been retained, but the velocity of its action has been moderated. The prolongation of the Insulin effect over the entire day not only adds mate-

rially to the comfort of the diabetic patient, but justifies the hope that the complications of diabetes may now be rendered less frequent in occurrence.

Protamine, Zinc & Iletin (Insulin, Lilly) is marketed by Eli Lilly and Company in 10-cc vials. Literature describing its clinical application will be promptly furnished upon the request of physicians.

Nutritional Anemia in Infants

The accompanying chart of the hemoglobin level in the blood of infants is based on more than 1,000 clinical cases studied by Mackay. The sharp drop in hemoglobin during the early months of life has also been reported by a number of other authorities. It is noteworthy that this fall in hemoglobin has been found to parallel closely that of diminishing iron reserve in the infant's liver.

The usual milk formula of infants in early life further contributes to this anemia because milk is notably low in iron. It is now possible, however, to increase significantly the iron intake of bottle-fed infants from birth by feeding Dextrin-Maltose With Vitamin B in the milk formula. After the third month Pablum as the first solid food offers substantial amounts of iron for both breast- and bottle-fed babies.

Reasons for Early Pablum Feedings

1. The iron stored in the infant's liver at birth is rapidly depleted during the first months of life (Mackay,¹ Elvehjem²)
2. During this period the infant's diet contains very little iron—1.44 mg per day from the average bottle formulae of 20 ounces, or possibly 1.7 mg per day from 28 ounces of breast milk (Holt³)

For these reasons, and also because of the low hemoglobin values so frequent among pregnant and nursing mothers (Coons,⁴ Galloway⁵), the pediatric trend is constantly toward the addition of iron-containing foods at an earlier age, as early as the third or fourth month (Blatt,⁶ Glazier,⁷ Lynch⁸)

The Choice of the Iron-Containing Food

1. Many foods reputed to be high in iron actually add very few milligrams to the diet because much of the iron is lost in cooking or because the amount fed is necessarily small or because the food has a high percentage of water. Strained spinach, for instance, contains only 1 to 1.4 mg of iron per 100 gm (Bridges⁹)
2. To be effective, food iron should be in soluble form. Some foods fairly high in total iron are low in soluble iron (Summerfeldt¹⁰)
3. Pablum is high both in total iron (30 mg per 100 gm) and soluble iron (7.8 mg per 100 gm) and can be fed in significant amounts without digestive upsets as early as the third month, before the initial store of iron in the liver is depleted. Pablum also forms an iron-valuable addition to the diet of pregnant and nursing mothers.

Pablum (Mead's Cereal thoroughly cooked and dried) consists of wheatmeal, oatmeal, cornmeal, wheat embryo, brewers' yeast, alfalfa leaf, beef bone, iron salt and sodium chloride.

KETONIC AND NON-KETONIC ESTROGENS ~

By W W WESTERFELD and EDWARD A DOISY, *St Louis, Missouri*

INTRODUCTION

ACTIVE experimental work on the internal secretion of the ovary began with the demonstration of Knauer ¹ in 1899 that transplantation of the ovary from its normal site did not produce atrophy of the uterus. Following these experiments many other investigators have made important contributions to our knowledge in this field. Adler,² Fellner,³ Hermann,⁴ Frank ⁵ and others prepared extracts which were active in producing growth of the uterus.

Two other investigations played an important rôle in the development of this field. The first was the introduction (Allen and Doisy ⁶) of the accurate and convenient method of assay by the vaginal smear reaction of rats and mice. The second was the discovery of Aschheim and Zondek ⁷ of the great concentration of estrogenic substances in the urine of pregnant women and mares.

The chemist, supplied with a rapid bioassay procedure and an abundant source of material, lost little time in showing his appreciation. Within the two years following the discovery of Aschheim and Zondek two pure crystalline estrogens were isolated from human pregnancy urine. The isolation in 1929 of the first crystalline estrogen was followed by a deluge of crystalline compounds with estrus producing properties until now some six or seven well characterized compounds have been isolated.

Only two of these estrogens, theelin and theelol, have been obtained from human urine. Although we have examined large quantities of human urine for other estrogens our experiments are thus far unsuccessful. On the other hand, the urine of pregnant mares contains at least six pure estrogens which have been isolated due mainly to the efforts of Girard ⁸ and of Wintersteiner and Schwenk ⁹. Curiously enough in spite of this large number, no theelol has been detected.

With the sole exception of the estriol obtained from human placenta (Browne ¹⁰) no other pure estrogen had been obtained from mammalian

tissues until in 1934 the question of the identity of the follicular hormone attracted our interest. We (MacCorquodale, Thayer and Doisy¹¹) expected to find theelin but instead obtained a reduction product of theelin, dihydrotheelin. Some of our findings may be of interest. About four tons of sow ovaries were extracted and the extract purified. Calculated as dihydrotheelin only about 25 mg were present in the four tons, a relationship of 1 part per 150,000,000. Approximately one half of the activity was recovered in a pure condition and the compound fully characterized. Recently, we have obtained good evidence of the existence of another estrogen in liquor folliculi of sow ovaries.

Chemically, the natural estrogens are closely related compounds which are derivatives of the cyclopentanophenanthrene ring systems. All are phenols and in addition each contains an alcoholic or ketonic radical. In our recent work we have applied methods to the study of the occurrence of the ketonic and non-ketonic estrogens. The formulas illustrate the relationship of these two forms.

Using Girard's¹² reagent which reacts with ketones to render them soluble in water and insoluble in ether it seemed that it might be possible quantitatively to separate the ketones from the alcohols as they occur in organs or in excreta.

Reactions of Theelin with Girard's Reagent and Semicarbazid

EXPERIMENTAL

Studies of mixtures of theelin and dihydrotheelin of known composition enabled us to apply Girard's reagent to quantitative work. Our data (table 1) lead us to believe that the separation is fairly accurate, but that the most likely error is in the possibility of obtaining low values for the ketonic fraction. Furthermore, confirmation of the results for the ketonic fraction can be obtained by treating this fraction with semicarbazid. This treatment causes the loss of at least 98 per cent of the activity of theelin.

TABLE I
Control of Methods

| Substance tested | Rat units of non-ketonic recovered | Rat units of ketone recovered |
|--|------------------------------------|-------------------------------|
| 1 0.436 mg theelin (870 R U) | <3 | 865 |
| 2 0.0425 mg dihydrotheelin (720 R U) | 700 | <5 |
| 3 Urine extract containing 300 R U dihydrotheelin plus 180 R U theelin | 360 | 130 |
| After semicarbazid treatment | 350 | <11 |
| 4 Urine extract containing 300 R U dihydrotheelin plus 250 R U theelin | 350 | 210 |
| After semicarbazid treatment | 340 | — |

Having worked out satisfactory methods for the quantitative separation of the ketonic from the non-ketonic estrogen, we investigated two interesting points: 1 the distribution of the two forms in ovaries and placenta, and, 2 the transformations that occur after the administration of pure theelin or dihydrotheelin.

KETONIC ESTROGENS IN TISSUES

Sow ovaries, from which the liquor folliculi and corpora lutea had been removed, were extracted with boiling ethyl alcohol. Purification was effected by methods commonly used in our laboratory. Upon fractionation between ketonic and non-ketonic estrogens it was found that a small but definite quantity of ketonic estrogen is present (table 2). This finding was confirmed by treatment with semicarbazid which destroyed the estrogenic property of the ketone.

TABLE II
Estrogens in Ovaries and Placenta

| Tissue | Total rat units | Non-ketonic rat units | Ketonic rat units |
|---|-----------------|-----------------------|-------------------|
| Sow ovaries after aspiration of liquor folliculi and removal of corpora lutea | 320 | 300 | 15 |
| Cow ovaries after removal of corpora lutea | 350 | 350 | <5 |
| Human placenta | | 600 | 200 |

Using the same methods, the study of cows' ovaries gave no evidence of the existence of a ketonic form, thereby adding one more item to species differences observed in studies of the follicular hormone

In spite of all of the chemical investigations of human placenta, there is no report of the isolation of any estrogen other than theelin. The extract of 10 placentas was purified. On a per kilo basis, the placenta contained about 800 rat units, of which approximately $\frac{1}{4}$ (200 R U) was ketonic. Since theelin is the ketonic estrogen in human pregnancy urine, probably theelin occurs in placenta. We expect to continue our work on human placenta with the purpose of isolating this ketone in crystalline form.

THE TRANSFORMATION OF ESTROGENS IN THE MONKEY

The development of the methods of separation of estrogens enabled us to study the transformations that occur in the organism. A common biochemical procedure in studying the metabolism of a compound is the administration of enough of the substance under investigation to exceed the destructive capacity of the organism thereby leading to the excretion of the original and intermediate products. The work of Zondek,¹³ of Mazer and Israel¹⁴ and others has shown that a large proportion of estrogens is destroyed or at least disappears and does not appear in the urine as estrus producing compounds. It was found that 3 mg of dihydrotheelin and 6 mg of theelin produced an excretion of sufficient quantities of estrogens for our study.

The disappearance of administered estrogens has led us to speculate on the organs in which destruction or transformation occurs. Since the estrogens exert specific effects in the female genitalia a natural supposition is that the hormones might be altered in those organs. Consequently, we have used for our study a normal adult female, an ovariectomized and an ovariectomized-hysterectomized monkey. It appears from our data in tables 3 and 4 that the destruction as measured by the excretion is not due to either the ovaries or uterus.

Each of the monkeys was injected for six consecutive days with the estrogen dissolved in oil. In the case of dihydrotheelin 0.5 mg was administered daily, in the experiment with theelin each monkey received 1 mg daily. Collection of urines by the use of metabolism cages was started on the day that the injections were begun and continued for ten days. Urines were collected over chloroform and each daily specimen was stored in the refrigerator until the experiment was terminated.

To effect the complete removal of estrogens the combined 10 day specimen was hydrolyzed with hydrochloric acid and extracted with ether. The ether solution was purified in the usual way and the separation of ketonic from non-ketonic estrogens carried out by the procedure already mentioned.

TABLE III

Estrogens Excreted after the Administration of 3 mg Dihydrotheelin

| Type of monkey studied | Non-ketones excreted (rat units) | | Ketones excreted (rat units) | | Ratio of R U non-ketones to ketones | Total excretion calculated as dihydrotheelin | |
|--------------------------|----------------------------------|--------------------|------------------------------|--------------------|-------------------------------------|--|------|
| | Total | After semicarbazid | Total | After semicarbazid | | Mg | % |
| Normal | 250 | 225 | 200 | <11 | 1 25 | 0 115 | 3 8% |
| Castrate * | 160 | 130 | 70 | <11 | 2 30 | 0 045 | 1 5% |
| Castrate Hysterectomized | 290 | 250 | 175 | <11 | 1 60 | 0 105 | 3 5% |

* Loss of some urine suspected

TABLE IV

Estrogens Excreted after the Administration of 6 mg Theelin

| Type of monkey studied | Non-ketones excreted (rat units) | | Ketones excreted (rat units) | Ratio of R U non-ketones to ketones | Total excretion calculated as theelin | |
|--------------------------|----------------------------------|--------------------|------------------------------|-------------------------------------|---------------------------------------|-------|
| | Total | After semicarbazid | | | Mg | % |
| Normal | 200 | 175 | 300 | 0 67 | 0 162 | 2 7% |
| Castrate | 210 | 200 | 200 | 1 00 | 0 112 | 1 97% |
| Castrate Hysterectomized | 275 | 250 | 600 | 0 46 | 0 317 | 5 3% |

Study of table 3 shows that from 1.5 to 3.8 per cent of the dihydrotheelin was eliminated in the urine. Of these quantities a fair proportion was ketonic, the ratios of non-ketonic to ketonic in terms of rat units being from 1.25 to 2.30.

Turning now to the data obtained following the injection of 6 mg of theelin, we find a slightly larger quantity of estrogen in the urine. In this case from 2 to 5.3 per cent of the theelin was eliminated as estrogenic material, of which a fair percentage was present in a non-ketonic form, presumably dihydrotheelin. A larger proportion of ketone was present in this experiment possibly due to the administration of twice as much estrogen.

We realize that our results with the normal monkey may be complicated due to the possibility of estrogen being formed in its ovaries. However, it is improbable that this animal produced much estrogen since the results on its urine are quite similar to those obtained on ovariectomized monkeys. This similarity of data also leads to the conclusion that the ovaries, uterus and tubes have very little influence on the excretion of administered estro-

gens It seems probable that other organs must play an important rôle in the transformation of estrogens

Our data indicate quite clearly that dihydrotheelin is convertible into a ketonic estrogen and that theelin, a ketone, is converted into a non-ketonic form Although the evidence is not complete our data indicate that the reaction between theelin and dihydrotheelin is reversible in the monkey

SUMMARY

By the application of Girard's reagent to the quantitative separation of ketonic from non-ketonic estrogens the following observations were made

- 1 A ketonic estrogen is present in sow ovaries
- 2 One-fourth of the estrogens in human placenta is ketonic
- 3 The existence of a ketonic estrogen in cow ovaries is doubtful, if present, the concentration is less than 5 units per kilo
- 4 When dihydrotheelin is injected into a normal adult, a castrate, or a castrate-hysterectomized monkey, 30 to 45 per cent of the excreted estrogenic activity is ketonic
- 5 When theelin is injected into a normal adult, a castrate, or a castrate-hysterectomized monkey, 30 to 50 per cent of the excreted estrogenic activity is non-ketonic The evidence indicates that in the monkey the reaction between theelin and dihydrotheelin is reversible and that the ovaries and uterus are not essential for this transformation

TREATMENT OF DIABETES MELLITUS WITH INSOLUBLE INSULIN COMPOUNDS

II HISTONE-INSULIN

By P A GRAY, M D , F A C P , FRITZ BISCHOFF, PH D , and W D SANSUM, M D , F A C P , *Santa Barbara, California*

THROUGHOUT the past two years we have been studying the effect of insoluble insulin compounds in the treatment of human diabetes mellitus. The clinical results obtained with insulin tannate and insulin-zinc compounds have already been reported¹. This communication deals with our clinical trial of the histone-insulin compound discovered and prepared for clinical use by one of us (F B²). This preparation has been found capable of controlling diabetes when used alone. Because of its slow and prolonged action on the blood sugar it is particularly useful in severe types of diabetes in juvenile patients and in elderly cases with cardiovascular complications.

HISTONE

The histones are one of a group of seven simple proteins, the others being the albumins, globulins, glutelins, prolaminnes, albuminoids and protamines. They are not coagulable by heat and although soluble in water and dilute acids, they are insoluble in ammonia, a feature which is characteristic. In common with the other five simple proteins and in contrast to the protamines they consist of a large number of amino acids. (Table 1)

TABLE I
Chemistry of Protamine and Histone

| | Protamine | Histone |
|-----------------------|-----------|--------------|
| Per cent nitrogen | 25-30 | 17 |
| Per cent histidine | Free | 5 |
| NH ₄ OH | Soluble | Precipitated |
| Sulphur | Absent | Present |
| Per cent amino acids— | | |
| Glycine | 0 | 0.5 |
| Alanine | 0 | 3.5 |
| Leucine | 0 | 11.8 |
| Proline | 11 | 1.5 |
| Phenylalanine | 0 | 2.2 |
| Glutamic acid | 0 | 3.6 |
| Tyrosine | 0 | 5.2 |
| Arginine | 87 | 15.5 |
| Lysine | 0 | 6.9 |

* Presented at the St. Louis meeting of the American College of Physicians, April 22, 1937.

From the Chemical Laboratories of the Santa Barbara Cottage Hospital and the Sansum Clinic, Santa Barbara, California.

The histone which was used clinically was prepared by the method of Kossel and Kutscher as modified by Bischoff² to reduce the ash content. This ash contains calcium and magnesium. Unknown constituents present in the material used clinically are less than 1 mg per 2500 units of insulin. Thymus glands, C P hydrochloric acid, ammonia water, alcohol and ether are the only substances required in the preparation of the histone.

The histone is added to commercial insulin at the acid side of the isoelectric point of insulin to form a solution. To this is added a disodium phosphate buffer solution which precipitates the histone-insulin on the alkaline side of the insulin isoelectric point. The pH of the solution at the time of injection approximates 6.7. The precipitate is finely divided and readily forms a suspension on shaking. A glass bead has been placed in the sterile, rubber capped vials to facilitate uniform mixture before injection.

Zinc and other metals of the H_2S group are definitely absent from the histone preparations which we have used. The only possible source of zinc would be from the commercial insulin used in the preparation of the combination.

MATERIAL

To date histone-insulin has been used clinically on 30 patients under controlled conditions. These patients have varied in age from 5 to 74 years and present all grades of severity of diabetes mellitus. All were hospitalized during part of the period of observation. Three of these patients have taken histone-insulin for the past three months consecutively. Sporadic observations are available on five additional patients.

TECHNIC OF ADMINISTRATION

Histone-insulin is injected subcutaneously with the ordinary syringe and needle into the same areas of the body as is commercial insulin. In several hundreds of injections only once has any local tissue reaction been noted at the site of injection. This consisted in an ephemeral erythema. No painful subcutaneous lumps have been encountered. Wells³ did not characterize histones as being allergenic. No patient has yet experienced any inconvenience from the injections, even of volumes up to 1.6 cc (of a U-50 strength).

When histone-insulin has been used alone to control a patient's diabetes one dose in 24 hours has usually sufficed. This dose is given either one-half hour before or immediately after breakfast. A few patients have required two doses in 24 hours. They have received three-quarters of the total dose after breakfast and one-quarter immediately before supper. Some patients have required a small dose of commercial insulin together with their daily dose of histone-insulin. This has been injected at the same time as the new preparation but with a separate syringe and into a different area of the body.

We recommend that the solution of histone-insulin be kept cool and that

it be shaken vigorously prior to each injection to insure uniform suspension of the insoluble insulin throughout the solution. The preparation used has been reasonably stable.

RESULTS

The observations of Bischoff³ that histone delays the absorption and prolongs the hypoglycemic action of commercial insulin have been confirmed in man. Figure 1 shows this effect. Under identical experimental conditions this diabetic patient's blood sugar level remained low for a longer period of time after a single injection of histone-insulin than after regular insulin.

FIG 1. M. B. A comparative study of the duration of action of regular insulin and histone-insulin in a diabetic male aged 24. On each test day the patient remained at bed rest. Forty units of insulin were given. One-half hour later he ate a breakfast containing C 97, P 27, F 44 and then fasted for the remainder of the test period. Evidence is presented that histone-insulin is absorbed more slowly, but acts over a much longer period than regular insulin.

In another group of experiments the physiologic effects of single doses of commercial insulin, protamine-insulin (zinc)⁴ and histone-insulin were compared on the same patient. The general plan of the experiments was as follows. Each subject ate the same food each test day at the same hour and either remained at bed rest or exercised uniformly. Each test day was separated from the others by a rest period of at least 24 hours. This was felt to be especially essential between the days on which the insoluble compounds were given in order to avoid any accumulative effect. Under the conditions

of the experiments where food was taken at regular intervals the blood sugar level reached its lowest point after a single injection of commercial insulin in four to four and a half hours, and after about ten hours had returned to the fasting level. In the case of both protamine-insulin (zinc) and histone-insulin the lowest point was reached between 14 and 24 hours after the injection.

Table 2 records the effect observed in a diabetic male aged 27. Food was served six times during the day, at 7 00 and 10 00 a m, 12 00 m, 3 00, 6 00 and 8 00 p m as indicated. One half hour before breakfast 45 units of insulin were given subcutaneously. Blood sugar levels were determined before the insulin was given and at three, five, seven and a half, eleven and a half, 15 and 24 hours thereafter. Urine was collected separately from 6 30 a m to 9 00 p m and from 9 00 p m to 7 00 a m the following morning. On the test day when regular insulin was given there

TABLE II

| Time | Food | | | Blood Sugar (mg %) | Urine Sugar (gm) | Blood Sugar (mg %) | Urine Sugar (gm) | Blood Sugar (mg %) | Urine Sugar (gm) |
|----------|------|----|----|-----------------------|-------------------------|-----------------------|-------------------------|-----------------------|-------------------------|
| | C | P | F | | | | | | |
| 6 30 a m | | | | 160 | | 158 | | 156 | |
| 7 00 | 48 | 28 | 23 | Insulin (45-U) | | Protamine (45-U) | | Histone (45-U) | |
| 9 30 | | | | 84 | | 244 | | 268 | |
| 10 00 | 10 | 0 | 0 | | | | | | |
| 11 30 | | | | 54 | | 188 | | 192 | |
| 12 00 m | 47 | 28 | 23 | | | | | | |
| 2 00 p m | | | | 150 | | 190 | | 174 | |
| 3 00 | 15 | 2 | 0 | | | | | | |
| 6 00 | | | | 240 | | 124 | | 154 | |
| 6 00 | 42 | 29 | 26 | | | | | | |
| 8 00 | | | | 206 | 8.9 | 78 | 0 | 120 | 15.3 |
| 7 00 a m | | | | | | 100 | 3 | 170 | 0 |

was no postprandial rise in the blood sugar after breakfast. The blood sugar reached its lowest level five hours after the injection, after which it rose. On both days when the insoluble insulin compounds were given there was a definite postprandial rise after breakfast with a subsequent gradual fall even though the patient continued to eat at the usual times. In the case of protamine-insulin (zinc) this secondary fall was more rapid than with histone-insulin. This difference was probably due to difference in the rate of absorption of the two compounds. Since the subject's blood sugar remained higher for a longer period of time after histone-insulin than after protamine-insulin (zinc), it was to be expected that a greater amount of sugar would be found in the first 12 hour urine specimen on this day. The lowest level of the blood sugar after both of the insoluble compounds was not reached until 15 hours after their injection.

Table 3 records another experiment of the type just described in a diabetic woman aged 53. In this case again the lowest level of the blood sugar after commercial insulin was reached five hours after the injection. After protamine-insulin (zinc) the blood sugar rose after breakfast to fall gradually, reaching its lowest level 24 hours later. After histone-insulin the post-breakfast rise did not occur, presumably because in this instance some free insulin was present in the mixture injected. The smaller amount of sugar present in the night collection of urine noted on each test day when the insoluble-insulin compounds were given suggests continued action, that is absorption of the compound, during the night.

TABLE III

| Time | Food | | | Blood Sugar (mg %) | Urine Sugar (gm) | Blood Sugar (mg %) | Urine Sugar (gm) | Blood Sugar (mg %) | Urine Sugar (gm) |
|----------|------|----|----|--------------------|------------------|--------------------|------------------|--------------------|------------------|
| | C | P | F | | | | | | |
| 6 30 a m | | | | 46 | | 76 | | 52 | |
| 7 00 | 56 | 21 | 33 | Insulin (40-U) | | Protamine (40-U) | | Histone (40-U) | |
| 11 30 | | | | 52 | | 276 | | 124 | |
| 12 00 m | 42 | 24 | 27 | | | | | | |
| 5 00 p m | | | | 252 | | 248 | | 180 | |
| 6 00 | 59 | 40 | 24 | | | | | | |
| 9 00 | 18 | 2 | 0 | | | | | | |
| 10 00 | | | | 412 | 14.6 | 332 | 17.6 | 344 | 24.5 |
| 7 00 a m | | | | 300 | 88.4 | 192 | 18.2 | 230 | 16.3 |

Table 4 records another similar experiment in a diabetic male aged 74. Here again the delayed absorption and prolonged hypoglycemic action of the insoluble-insulin compounds as contrasted to regular insulin is apparent. As in the preceding two experiments the subject's blood sugar level 24 hours after a single injection was not quite so low after histone-insulin as after protamine-insulin (zinc).

TABLE IV

| Time | Food | | | Blood Sugar (mg %) | Urine Sugar (gm) | Blood Sugar (mg %) | Urine Sugar (gm) | Blood Sugar (mg %) | Urine Sugar (gm) |
|----------|------|----|----|--------------------|------------------|--------------------|------------------|--------------------|------------------|

In all our experiments of this type some action on the blood sugar has been noted 24 hours or more after a single injection of the insoluble compounds. Although individual patients have shown some variation, protamine-insulin (zinc) and histone-insulin have, in general, behaved similarly.

Prior to using histone-insulin the 30 patients upon whom we have sufficient data required 2.7 average injections of commercial insulin daily, while on the new compound 1.2 average injections have sufficed to maintain a comparable degree of control. Various patients have received histone-insulin from a few days to three months continuously. Certain patients have received it intermittently over a year. We have studied principally a group of severe cases, many of them children, because it is obvious that in a high-dosage case requiring multiple injections daily a slow acting insulin would be most useful. Furthermore such cases have been the ones most available to us for such study. The ensuing protocols will show that in addition to reducing the numbers of injections required daily, the histone-insulin has reduced the fluctuations in the patients' blood sugar levels from one part of the day to another. In certain mild cases the effect of a single dose has apparently lasted throughout 48 hours. Recently we have carried several patients through both major and minor surgery by giving them daily injections of histone-insulin supplemented by small amounts of commercial insulin.

Histone-insulin and protamine-insulin (zinc) have had the same relative effect on this group of patients. Certain patients have been changed from one to the other easily with only minor readjustments. Some who have not been satisfactorily controlled with one of these new compounds have been with the other. The principal difference noted thus far in their clinical effect has been in the frequency of hypoglycemic reactions the morning of the day following the injection. Such reactions have been somewhat more frequent with protamine-insulin (zinc) than with histone-insulin. The recent review of the literature on protamine-insulin by Wilder⁵ makes further discussion of this preparation unnecessary.

HYPOGLYCEMIC REACTIONS

In appropriate dosage histone-insulin is capable of inducing characteristic hypoglycemic reactions. These usually appear 24 hours after a single injection and coincide with the peak of the depression of the blood sugar. Since the histone-insulin is injected just before or after breakfast, reactions have usually occurred at a corresponding time the ensuing morning.

The mildness of somatic manifestations is noteworthy. Sweating and trembling have been seen rarely. Drowsiness, headache and dizziness are the principal symptoms. Children have, on occasion, been hard to awaken and when finally awake have complained only of headache. We have occasionally seen children who presented no external manifestation of any kind.

and who seemed to be sleeping naturally, at a time when their blood sugar was at shock level

Relief of hypoglycemic shock has been accomplished in the same manner as after commercial insulin. This difference, however, is worthy of note. Whereas a single dose of readily available carbohydrate usually suffices in the case of regular insulin, repeated doses may be required after histone-insulin, due to late and continued absorption. This phenomenon has been seen in hypoglycemic shock produced by other insoluble insulin compounds.

COMMENT

In this study we have been concerned primarily with determining the role of histone-insulin in the treatment of human diabetes mellitus. Its ability to replace regular insulin as an agent in controlling diabetes has been demonstrated. Considerable individual variation has been noted among the patients studied. In the majority an adequate degree of control has been attained with one dose each 24 hours. Some cases which could not be controlled on one dose have been controlled on two doses. A few others could not be adequately controlled with any practical dosage scheme; these patients have discontinued taking histone-insulin and have resumed regular insulin. In every case studied we have tried to effect control of glycosuria with one dose in 24 hours, or a combined dose of new and regular insulin taken simultaneously. When this has not been possible patients, as a rule, have preferred to return to two (in some cases even three) injections of regular insulin than to continue with the same number of injections of the new preparation.

A control group of patients comparable in number and severity of diabetes to those receiving histone-insulin have been given protamine-insulin (zinc). Our clinical impression at present is that the two groups have behaved quite similarly. Histone-insulin and protamine-insulin (zinc) each have yielded good results in some patients and not in others. They both delay the absorption of insulin. The same patient can be controlled with either preparation and changed from one to the other with only minor adjustments of unitage. Thus far three patients have experienced distressing local reactions at the site of injection of protamine-insulin (zinc), sufficient to warrant the discontinuance of the preparation. None such have been encountered with histone-insulin. Some patients whose diabetes could not be controlled with one dose in 24 hours of one preparation have been controlled satisfactorily when changed to the other.

Our experience with histone-insulin to date has been too limited to warrant any statement concerning the glucose value of one unit of the new insulin compared to that of the old. Some patients in this group have required fewer total units of histone-insulin than of regular insulin on the same diet, the majority have required about the same number and some have required more.

Our records show considerable daily variation in the amount of glycosuria and the level of the blood sugar in those patients whose blood sugar on regular insulin rises during the night. Since the action of histone-insulin is comparable to that of regular insulin² when injected intravenously we have assumed that these irregular variations are due to variable absorption on different days. This difficulty is common to all of the insoluble insulin compounds with which we have worked.

PROTOCOLS

Case 1 J. G., a male, aged 37, has had diabetes for 15 years and angina pectoris for three years. He has been under continuous observation since May 1934. During this period he has never been consistently sugar free, his insulin has been administered in four doses, varying between 66 and 80 units. Normal fasting blood sugar levels have only been obtained when insulin has been given during the preceding night. Before starting the histone experiment this patient had seldom been free of precordial pain on effort for more than 24 hours at a time between 1933 and 1936. Electrocardiograms taken at various intervals have shown a high take-off and rounding of ST₁ and ₂ and depression of T₄ below the isoelectric line. The blood pressure has fluctuated between 140 to 150 systolic and 90 to 100 diastolic. It has been demonstrated that this patient would experience anginal pains whenever his blood sugar fell below 100 or rose above 300 mg per cent. Attacks have been induced at will by inducing fluctuations in his blood sugar and relieved without the aid of vasodilators by restoring the blood sugar to normal.

Table 5 shows that this patient was gradually changed from commercial insulin to histone-insulin. It has sufficed to control his diabetes. One dose per day has replaced four of commercial insulin and effected a comparable degree of control. The number of units of histone now taken daily at one injection approximates those formerly distributed in four. In spite of large volumes of histone-insulin having

been injected over several months' time no local or systemic reactions have been encountered. The only clinical manifestation of hypoglycemic shock has been headache and dizziness. Since taking histone-insulin this patient has not experienced anginal pain at any time (now over two months), in spite of the fact that his blood sugar level has occasionally attained that known previously to induce an attack. A recent electrocardiogram has been reported to be negative.

Case 2 P R, a boy, aged 14, has had diabetes for five years and has been under continuous observation during this time. On a maintenance diet his 24 hour urine specimens have usually been sugar free. His daily insulin requirement has been about 57 units, given in four doses, for the past three years.

This patient has been changed over to histone-insulin. As shown in table 6 it has sufficed to control his diabetes satisfactorily when injected once daily. Ten to 20 per cent more units per day have been necessary than formerly. The only clinical manifestation of hypoglycemia has been headache. No local reactions at the site of injection have been noted.

The horizontal divisions of table 6 indicate separate periods of hospitalization. The final one (3-26-37) followed an attack of scabies. Loss of carbohydrate toler-

ance during infections is not prevented by using the new insoluble insulin compounds. This observation has been amply confirmed during the recent epidemic of upper respiratory infections.

This patient has received the largest volume of the histone-insulin preparation. While taking it he has gained in weight, felt well, and exhibited no untoward local or systemic effects.

Case 3 B A, a diabetic girl, aged 5 years, was admitted to the hospital in diabetic ketosis. One hundred fifty units of insulin were given during the first 24 hours. After recovery from ketosis the patient was controlled on commercial insulin.

Table 7 shows how this patient was changed over to histone-insulin. One month later a smaller total number of units sufficed to control her diabetes than on commercial insulin. She had gained 2 kg in weight during the period of observation.

Once while receiving 40 units of histone-insulin this child went into hypoglycemic shock under conditions which may well occur in other patients on home management. She awoke one morning feeling queerly. Her mother, failing to recognize any unusual behavior, gave the usual dose of histone-insulin a few minutes before breakfast as customary. Before breakfast could be eaten the child was unconscious. When readmitted to the hospital the child exhibited an interesting wave-like response to treatment. For a while after the administration of glucose she would arouse, appear normal, talk rationally, drink orange juice, and then sink back into a stupor. This phenomenon continued for 36 hours, indicating a delayed absorption of the histone-insulin. Recovery was complete with no demonstrable ill effects.

Case 4 S. H., a man, aged 74 years, has had diabetes 18 years. Before using histone-insulin there had been no apparent change in his carbohydrate tolerance for many weeks, and the usual insulin requirement was about 50 units. Throughout the three different periods when he received histone-insulin he was confined to bed on account of vascular changes in the extremities. On each trial ranging from two to four weeks one dose of histone-insulin per day controlled his diabetes. Table 8 gives a synopsis of these three different experimental periods.

Figures in **boldface type** indicate Histone

SUMMARY

Histone-insulin is capable of controlling human diabetes mellitus when used alone. Its action on the blood sugar is more delayed and prolonged

than that of commercial insulin. No local or systemic reactions have been noted even with injection of a large volume or over long periods of time. In a group of 30 patients an average of 2.7 injections of commercial insulin per day has been reduced to an average of 1.2 injections of histone-insulin.

We are indebted to Mr W R Dickinson of Hope Ranch Park, Santa Barbara, for a grant to cover the preparation of the histone used in this study and to Eli Lilly and Company for a generous supply of insulin.

ACACIA THERAPY IN NEPHROTIC EDEMA

By MICHAEL J. LEPORE,[†] *Bronx, New York*

DURING the past decade evidence has accumulated from many quarters lending support to the physico-chemical concept of edema formation advanced originally by Starling¹ in 1895. The basis of this theory is that capillary pressure and serum colloid osmotic pressure are opposing forces, the balance between which determines the direction of movement of fluid and of the crystalloidal constituents of the blood across the capillary wall. In view of the numerous excellent papers on the subject, it is needless to review the evidence establishing the validity of the Starling concept in explaining the mechanism of production of nephrotic edema. The lowering in serum albumin concentration and hence in serum colloid osmotic pressure, seen in nephrosis, nutritional edema and similar states is, according to the Starling theory, the major factor determining the incidence of edema in these conditions.

Rational attempts to remove nephrotic edema have, therefore, been aimed at raising the serum colloid osmotic pressure. Transfusions of whole blood, serum or plasma have been used. High protein diets have been given in an attempt to raise serum protein levels by stimulating regeneration of protein. Artificial colloidal substitutes for serum proteins have been proposed, gum acacia being the most popular. Hartman and associates² reported favorably on the use of gum acacia in the treatment of nephrosis in children. In five of six cases, they found that when other measures had failed, the intravenous injection of acacia resulted in the initiation of diuresis. They asserted that the aim of acacia therapy is to raise the serum colloid osmotic pressure to a level of about 17 cm. of water, and in this way to reverse the process of transudation so that absorption of edema fluid is favored. Failures they thought were due to insufficient dosage of acacia. They advocated giving doses of one gram of acacia per kilogram of ideal body weight in the form of a 15 per cent solution.

In 1935, Dick and associates³ recorded discouraging experiences with acacia in the management of nephrotic edema, reporting that acacia was often ineffective in causing diuresis, and that a fall in serum protein concentration and a progressive anemia followed its use. They especially stressed the fact that the decrease in serum protein concentration was of such magnitude as to negate any rise in colloid osmotic pressure produced by the presence of acacia in the serum, the net result being appreciable decreases in the calculated serum colloid osmotic pressure. They reported furthermore

* Received for publication February 8, 1937.

From the department of Internal Medicine, Duke University School of Medicine, Durham, North Carolina.

[†] Research Fellow of the American College of Physicians.

that following its intravenous injection acacia could be demonstrated in appreciable concentrations in pleural and peritoneal fluids of their patients. Moreover, while the first course of acacia injections was often effective in relieving edema, subsequent injections proved ineffective. Inspection of their protocols reveals that they used adequate amounts of acacia, for relatively massive dosage was employed.

In support of their clinical observations, Dick and associates reported several experiments on dogs. Four dogs were given acacia intravenously, following which the serum protein concentrations of all four animals decreased considerably. With cessation of the acacia injections, the serum proteins returned to normal. There was a distinct tendency in their experiments for both albumin and globulin fractions to vary in the same proportion. The possibility that these results were dilution effects was dismissed by them without the presentation of adequate evidence in support of their interpretation. They concluded that "the use of acacia intravenously in patients with nephrosis was not found of value and was associated with undesirable results."

It is the purpose of this communication to report four instances of nephrotic edema in adults treated with acacia. Certain of the phenomena reported by Dick and associates³ were encountered in these cases, but in the light of actual measurements of the plasma volume, it has been possible to interpret them differently. Two cases (Case 3, M. W., and Case 4, Z. R.) fulfilled the classical requirements for the diagnosis of so-called lipid nephrosis. The other two were definitely cases of chronic active glomerulonephritis in the nephrotic stage.

METHODS

The plasma protein analyses were done by the method of Howe.⁴ The plasma volume measurements in the first three cases were made with the method of Rowntree and associates⁵ as modified by Whipple and associates.⁶ There are certain objections to this method which have been considered in some detail in another report.⁷ However, experience with an improved technic⁷ confirms the general trend of the observations made with the older method and, furthermore, the magnitude of most of the changes to be reported is well beyond the errors inherent in the older method. It has been explained elsewhere⁷ that values for plasma or serum volume obtained by the dye method are not absolutely accurate for they include a small volume of lymph. For this reason, in the present report, emphasis has been placed on the *changes* in serum or plasma volume occurring in the same patient rather than upon the actual values obtained.

Determinations of plasma volume were done on patients who had been fasting for three or more hours and were lying flat in bed. In Case 4, the serum volume measurements were made with the improved method.⁷

Acacia in saline (Lilly) was given in the concentrations stated below. On one occasion acacia without saline was used.

RESULTS

Case 1 V B, white, male, aged 16 years

History Admitted to Duke Hospital on October 13, 1934 complaining of "swelling of the face, ankles, and stomach" of one month's duration. The onset of illness was referred to a "cold" which came on shortly after wading in cold water while swimming. Swelling of the ankles and puffiness of the eyelids were noted on the day following the onset of the cold. The urine, examined on the fifth day of illness by his doctor, boiled solid. He was placed on a low protein diet with fluids restricted and was given magnesium sulphate by mouth. The edema at first diminished but soon recurred and during the week prior to admission had become progressively worse.

Physical Examination Blood pressure, 144 mm of Hg systolic and 110 diastolic. Marked edema of the eyelids is present. There is considerable pre-sacral and pre-tibial pitting edema. Signs of bilateral pleural fluid and of moderate ascites are elicited. The optic fundi show no exudate or papilledema. The tonsils are considerably enlarged and appear chronically infected. No evidence of cardiac failure is present.

Urine Specific gravity 1.035, dark brown, albumin four plus. Microscopic 10 to 12 red blood cells per high power field. Occasional granular cast.

Blood Hemoglobin 16 grams per 100 c.c. Red blood cells 5,570,000 per cu. mm. Blood non-protein nitrogen 34 mg. per cent. Total plasma proteins 3.54 gm. per 100 c.c., plasma albumin 0.67 gm. per 100 c.c., plasma globulin 2.87 gm. per 100 c.c., cholesterol 375 mg. per 100 c.c. Wassermann and Kahn reactions negative.

Kidney function tests Phenol red excretion, 65 per cent excreted in two hours (October 14). Urea clearance, 145 per cent of normal, October 16, 1934 and 95 per cent of normal, October 22, 1934.

Basal metabolic rate minus 27 per cent (October 16, 1934).

Therapy The patient was placed on a high protein, salt-free diet and was kept in bed. The edema remained unchanged. On October 20, 1934, he was given intravenously 45 grams of acacia in saline as a 15 per cent solution. At the end of the infusion, slight urticaria appeared and the proximal phalangeal joint of the right index finger appeared tense and swollen. No febrile reaction occurred. The urticaria and joint swelling subsided after the injection of a total of 0.6 c.c. of a 1-1000 solution of adrenalin. This injection of acacia was followed by an almost immediate and persistent large diuresis. Another 30 grams of acacia in saline as a 15 per cent solution were given on October 22, 1934. The further sequence of events is illustrated in figure 1. It is there seen that after the injection of acacia the plasma volume rose markedly and the plasma protein concentration and cell volume fell, presumably as a result of hemodilution. Diuresis continued as shown. This patient was followed at monthly intervals for another six months and during this time remained practically free from edema on an active regime despite the persistence of marked albuminuria and a low serum albumin concentration. Clinically demonstrable hepatic enlargement was at no time present.

Case 2 D J, colored male, aged 26

History Admitted April 9, 1935 with the complaint of "swelling of the body" of two months' duration. His illness began two months before when he first noted the insidious onset of puffiness of the eyelids and ankles. Smoky urine was also noted at this time. He kept on with his usual activities and the edema soon became generalized. Five weeks after the onset of his initial symptoms, he consulted a

doctor who told him that he had kidney trouble and prescribed a meat-free diet with limited salt. Progressively increasing edema led him to enter the hospital.

The past history reveals the fact that he has had occasional attacks of sore throat. However, he does not remember having had a sore throat with the onset of the present illness. He had a chancre 10 years ago for which he received no anti-luetic therapy.

FIG 1

Physical Examination Blood pressure, 186 mm of Hg systolic and 90 diastolic. There is considerable edema of the face and hands. A moderate amount of ascites, and pre-tibial and pre-sacral soft, pitting edema are present. The tonsils are moderately enlarged and seem chronically infected. The heart is moderately enlarged to the left and the sounds are forceful. The liver is not palpable. The fundi oculi show slight bilateral papilledema. No exudates are seen.

Urine Reddish brown, specific gravity 1.016, albumin four plus. Microscopic: Many red blood cells, numerous leukocytes, many coarse granular and hyaline casts.

Blood Hemoglobin 13.6 gm per 100 cc Red blood cells 3,880,000 per cu mm
 Blood non-protein nitrogen 33 mg per cent Total plasma proteins 4.27 gm per 100 cc
 Plasma albumin 1.44 gm per 100 cc Plasma globulin 2.83 gm per 100 cc
 Cholesterol 911 mg per cent Wassermann and Kahn reactions four plus

Kidney function tests Phenol red excretion 65 per cent in two hours Urea clearance, 51 per cent of normal April 16 and 46 per cent of normal May 8

FIG 2

Basal metabolic rate, minus 24 per cent (April 11)

Therapy The patient was placed on a high protein, low salt diet. On April 10, 1935, 500 cc of 6 per cent acacia in normal saline were given intravenously, and the dose was repeated on April 11 and April 14. Diuresis occurred immediately after the first dose of acacia and progressed as shown in figure 2. Another 45 gm of acacia in saline in 10 per cent solution were given on April 17.

Following the acacia injection, as is seen in figure 2, the plasma volume increased considerably, while the cell volume and plasma protein concentration fell, apparently a dilution effect. At the end of the diuresis, the plasma volume diminished in this case and the plasma protein concentration and cell volume rose at the same time. The patient lost a total of 17.2 kilograms of edema fluid during the course of his diuresis. His blood pressure decreased rapidly and remained about 140 systolic and 70 diastolic.

Clinically, there was some evidence that tonsillitis was the factor responsible for the renal lesion. However, in view of the presence of syphilis, cautious anti-syphilitic therapy was initiated including potassium iodide, several doses of bismuth and finally two doses of neoarsphenamine. The patient was improving until on May 12, 1935 he developed tonsillitis. On May 14, 1935 a peri-tonsillar abscess was incised with the liberation of considerable pus. The infection spread rapidly in spite of therapeutic measures and at the same time an acute exacerbation of his nephritis occurred with nitrogen retention. He was discharged against advice on May 12, 1935, his blood non-protein nitrogen having rapidly risen to 90 mg per cent. He died at home the next day.

Case 3 M. W., aged 44, white male

Admitted first on January 8, 1935. Three weeks prior to admission the patient had noted the insidious onset of swelling of the feet and rapid gain in weight. Two weeks before admission, he consulted his doctor who told him he had kidney trouble and placed him on a meat-free, salt-free diet. Edema became progressively worse and he was, therefore, referred to the hospital.

The patient states that he has always enjoyed good health. He has been a rather heavy drinker of corn liquor. There is no history of sore throats, upper respiratory infections or exposure to heavy metals. No history of hematuria.

Physical Examination Blood pressure, 120 mm of Hg systolic and 80 diastolic. A well developed large man weighing 118 kilograms. There is marked pretibial and presacral pitting edema. The heart and lungs are clear. The fundi oculi are normal.

Urine Specific gravity 1.027, albumin 4 plus, no red blood cells. Numerous white blood cells, many small and medium coarse and fine granular casts. No red blood cells on repeated examinations.

Blood Hemoglobin 15.8 gm per 100 cc. Red blood cells 5,030,000 per cu mm. Non-protein nitrogen 31 mg per cent. Total plasma proteins 3.78 gm per 100 cc. Plasma albumin 1.20 gm per 100 cc. Plasma globulin 2.58 gm per 100 cc. Cholesterol 500 mg per 100 cc. Wassermann and Kahn reactions negative.

Kidney function studies Concentration test, maximum concentration 1.027 (corrected for albumin). Urea clearance, 104 per cent of normal (January 9).

Basal metabolic rate plus 3 per cent (January 12).

Therapy He was placed on a high protein low salt diet. On January 11, and again on January 12, 14 and 16, 500 cc of 6 per cent acacia in normal saline were given intravenously. Diuresis occurred following the first injection of acacia and continued as shown in figure 3. At the patient's insistence, he was discharged on January 19, his edema having diminished considerably.

It is seen from figure 3 that following the acacia injection, a large increase in plasma volume occurred with an associated fall in cell volume and plasma protein concentration.

Readmission Readmitted on April 10, 1935 with the complaint of recurrence of edema.

While adhering to the diet following discharge on January 19, 1935, the patient continued to lose edema and his weight reached a low point of 106.7 kilos. However, several weeks after discharge, he resumed his activities and ceased to follow

dietary instructions. Edema returned and he consulted several physicians who, after various therapeutic measures had been tried without success, referred him to the hospital for treatment.

Physical Examination Blood pressure 120 mm of Hg systolic and 70 diastolic. The patient is more edematous now than he has ever been. He weighs 126.25 kilos and later events show that at least 36 kilos of this weight consist of edema fluid.

FIG 3

The scrotum is tremendously distended, measuring 102 cm in circumference. Ascites is present. There is no evidence of cardiac failure.

Urine: Specific gravity 1.020, albumin four plus. Microscopic, as before, no red blood cells.

Blood Hemoglobin 14 grams per 100 e e Red blood cells, 4,400,000 per eu mm
 Non-protein nitrogen 35 mg per cent Total plasma protein 3.41 gm per 100 c c
 Plasma albumin 0.71 gm per 100 c c Plasma globulin 2.70 gm per 100 e e

Kidney function studies Urea clearance 97 per cent of normal (May 5)

Basal metabolic rate minus 25 per cent (May 10)

Therapy The patient was placed on a high protein salt free diet. Acaia was given at the times and in the quantities and concentrations indicated in figure 3. On April 16, 0.5 e e of salyrgan was given intravenously. On April 22, salyrgan 1.0 c c was given intravenously. Between April 15 and 20, the patient also received a total of 37 gm of potassium chloride by mouth. It is difficult in the face of the employment of several different diuretic agents to evaluate their respective roles in the production of the moderate diuresis which occurred between April 10 and 24. On April 25, 500 c c of 6 per cent salt free acacia in distilled water were given intravenously. This injection was followed by a severe chill lasting 30 minutes and a temperature rise to 39.2° C. A period of oliguria lasting about 10 to 12 hours ensued. However, this was succeeded by a marked and rapid diuresis. The plasma volumes charted as of April 25 and April 27 are not actual measurements but are calculated on the basis of observed hemoglobin concentration changes. They indicate that following the injection of the last 30 gm of acaia, a large rise in plasma volume occurred. Toward the end of the diuresis the plasma volume returned to below the initial figure. By this time, the patient had lost 23 kilos, but still had edema. Ammonium chloride was started on May 5, 1935 and the patient gradually lost another 12 kilos of edema fluid. He was discharged almost edema free on June 6, 1935. His liver was not palpable during either admission.

Case 4 Z R, white female, aged 22

The patient was admitted on November 11, 1936 with the complaint of "kidney trouble". In January 1936 the patient noticed the insidious onset of edema of the ankles. Several days later she first complained of a severe sore throat. Her urine was found to contain large amounts of protein. Her family physician advised tonsillectomy which was performed on January 10. The patient remained in bed for one month during which time edema remained marked. She resumed her household activities in February 1936 and ate a normal diet. She continued to have edema of the legs and face which became more severe despite the employment of a wide variety of therapeutic measures. The patient was therefore referred to this hospital for treatment.

Physical Examination Blood pressure 110 mm of Hg systolic and 70 diastolic. The patient is a well developed young white woman. There is marked pitting edema of the subcutaneous tissues from the level of the tenth dorsal vertebra down. There is a small amount of pleural fluid in the right chest. A moderate amount of ascites is also present. The fundi oculi are normal. The heart is normal. The liver cannot be felt.

Urine Amber, specific gravity 1.029, albumin three plus. Microscopic Many hyaline casts, rare red blood cells, occasional white blood cell.

Blood Hemoglobin 14.6 grams per 100 c c Red blood cells 5,380,000 per cu mm
 Non-protein nitrogen 40 mg per cent Total serum proteins 3.70 gm per 100 c c
 Serum albumin 0.80 gm per 100 c c Serum globulin 2.90 gm per 100 c c Serum cholesterol 621 mg per cent Serum chlorides 554 mg per cent Blood Wassermann and Kahn reactions negative

Kidney function tests Urea clearance 67 per cent of normal (Dec 4, 1936) and 77 per cent of normal (Dec 22, 1936)

Basal metabolic rate minus 12 per cent (Dec 2, 1936)

Therapy The patient was placed in bed and given a diet low in salt and containing 60 gm of protein per day. On December 10, 1936 the diet was changed to

120 gm of protein and urea, 60 gm per day by mouth, was given as a diuretic. Since no marked diuresis occurred on this regime, urea was discontinued on December 15, 1936 and acacia injections were started on December 17, 1936. As can be seen in figure 4, diuresis followed the second injection of 500 cc of 6 per cent acacia in normal saline. The patient lost a total of about 10 kilos of edema fluid in seven days and was practically edema free when discharged on December 24, 1936.

FIG 4

DISCUSSION

Serum Volume Changes and Diuresis When acacia in the concentration of 6 per cent or more is introduced into the blood stream of patients with hypoproteinemia, an immediate increase in plasma colloid osmotic pressure and in plasma volume must of necessity occur. However, the increase in

the plasma colloid osmotic pressure will cause fluid to be attracted to the blood stream and when a state of equilibrium is attained, it may well be that the increase in plasma volume will effectively counterbalance the original increase in plasma colloid osmotic pressure. The final result will, therefore, be an increase in the plasma volume and in the total circulating plasma colloid.

In the present report, the studies of plasma volume have been performed at times significantly distant from the acacia injections, since in this way the more permanent effects of acacia could be investigated. The striking feature of the results is that almost without exception, the persistence of diuresis following the injection of acacia was associated with increase in the plasma volume. In the absence of actual measurements of plasma colloid osmotic pressure, it is impossible to say whether it, too, increased during the periods of diuresis and hypervolemia. However, the decrease in plasma protein concentration noted during the same periods would indicate that if any rise in plasma colloid osmotic pressure did occur, it was probably of small magnitude. Since the most consistent change following acacia injection was the increase in plasma volume, it seems logical to suspect that this change was the one responsible for diuresis. This suggestion was originally advanced by Peters⁸ in a stimulating discussion of the mechanism of acacia diuresis in nephrosis which concluded with the statement that "It may well be the fullness of the blood stream which provokes the diuretic response on the part of the kidneys."

The manner in which the "fullness of the blood stream" provokes diuresis is not apparent from the data at hand. It is, however, probable that the diuresis associated with increases in plasma volume is due to increased filtration of urine. This may be due to the opening of more glomeruli by the larger volume of blood or to an increase in the rate of blood flow through the kidneys. In the absence of actual measurements of these variables, the mechanism provoking diuresis must remain obscure.

If increase in plasma volume provokes diuresis in nephrotic states, some of the so-called "spontaneous" diureses which we occasionally see may thus be explained. When these diureses have occurred in the absence of any change in the plasma protein concentration, they have usually been classed as exceptions to the Starling theory. However, we now have evidence that large fluctuations in plasma volume and hence in the total circulating colloid may occur in nephrotic states without any changes in the plasma protein concentration.⁹ During the "spontaneous" diureses, despite constant plasma protein concentrations, large rises in the total circulating colloid may have occurred. Such rises would act much like acacia in initiating and maintaining diuresis. Our data do not support the view that the absolute volume of the plasma at any given time is the factor responsible for diuresis. However, they do support the thesis that acutely induced increases in the plasma volume provoke diuresis. The cause for this is probably to be found in the fact that gradual changes in plasma volume are compensated for,

while the more acute changes exceed, for a time at least, the ability of the body to compensate

Serum Protein Changes Following the injection of acacia, in accord with the report of Dick and associates,³ the plasma protein concentration decreased. This change was due in part to hemo-dilution. However, in three instances, hemo-dilution alone did not account for the decrease in plasma protein concentration. Measurements of the plasma volume in these patients revealed that the *total circulating plasma protein* (derived by multiplying the plasma volume by the plasma protein concentration), had actually decreased following the injection of acacia. It is not to be inferred that the regeneration of plasma protein was impaired, for in one carefully studied case,¹⁰ regeneration of plasma protein remained active following the use of acacia. However, with diuresis, the urinary loss of protein increased sufficiently to account for the observed reduction in the total circulating plasma protein. The explanation for this increase in proteinuria is not evident but is now being sought in this clinic. At present, it is our belief that the increased proteinuria following acacia injection is due to increased glomerular filtration and not to a toxic action of acacia on the glomeruli. In accord with this belief are the data of Bing¹¹ who has suggested that changes in the degree of proteinuria in the same patient reflect changes in glomerular filtration.

Red Cell Volume Changes The decrease in red cell volume following acacia therapy is largely a dilution effect.

Practical Considerations It is apparent that in the cases here reported, diuresis was provoked by acacia in much smaller quantities than those used by others.²⁻³ Our studies indicate that the aim of acacia therapy is to increase the plasma volume, and this may be attained with relatively small dosage of acacia. We are now using intravenous injections of 500 c.c. of 6 per cent acacia in normal saline as a dose for average adults, and this is repeated at daily intervals for three or four days. If acacia is going to be effective, results should be apparent with this dosage in most cases. We see no point in forcing dosage much past this limit if no diuresis has resulted. If diuresis does occur, 30 gram doses may be repeated at intervals which will of necessity vary with individual cases. The plasma albumin level should be watched closely and if it falls too sharply, acacia therapy should be discontinued until the albumin level has been substantially improved.

In selecting cases for acacia therapy, the following suggestions may be of value. A previous adequate trial on a high protein salt-poor diet and diuretics such as urea or members of the saline diuretic group is definitely indicated in all cases. These therapeutic measures may well be supplemented with others aimed at increasing the plasma volume and plasma proteins, e.g., transfusions of whole blood, serum or plasma. If these measures fail, acacia therapy should be considered. Should an untoward reaction occur, the safest procedure is to stop using acacia. The use of acacia need not be

limited to cases of so-called nephrosis, for our results have been equally good in cases of chronic active glomerulonephritis in the nephrotic stage

CONCLUSIONS

1 Acacia provokes diuresis in nephrotic edema by increasing the plasma volume

2 A method of administration of acacia is presented, based upon the above concept of its mode of action, and involving the use of relatively small doses

3 The so-called deleterious effects of acacia described by other writers have been explained on grounds other than those of toxicity of acacia

4 Acacia has a definite place in the therapy of properly selected cases of nephrotic edema

I am deeply indebted to Dr John P Peters for his valuable advice

RECENT STUDIES ON THE EXCRETION OF MALE SEX HORMONES IN MAN ⁴

By F C KOCH, *Chicago, Illinois*

ALTHOUGH androsterone and dehydroandrosterone, two substances of androgenic character, have been separated from human urine, very little is known as to the significance of their occurrence and still less as to the fluctuations in the rate of excretion in health and disease. It is generally assumed that these substances are waste products formed from testosterone secreted into the blood stream by the gonads, but it is just as reasonable to expect that one or both of these urinary products may be precursors of testosterone or that they, or still other androgenic substances, may originate in part in other tissues or be present in our food.

A survey of the literature ¹ reveals that too many investigators have attempted to answer some of these questions by extraction and biological assay methods which are practically worthless for quantitative purposes. In this paper I propose to present a summary of some of the results which my colleagues and I have published on this problem in more detail elsewhere ^{1, 2, 3}.

By means of the comb-growth response in the capon ⁴ and a complete extraction procedure for urine, ⁵ we arrive at values which are distinctly higher than the highest reported elsewhere and 20 to 60 times the lowest reported by others ^{6, 7}. Our higher values are due to two factors—the complete extraction of the urine, the liberation of androgenic activity by acid hydrolysis from what appears to be a conjugated form, and the prevention of the subsequent destruction thereof by acid by limiting the hydrolysis to the time of maximum yield ³. Table 1 clearly shows that 15 minutes' acid-hydrolysis leads to a 70 to 160 per cent increase in androgenic units, but that two hours' boiling again leads to a loss of activity. The nature of the con-

jugated form, of the destructive process, and the significance of the conjugation, remain to be determined

Our studies on normal men and women covered urine collections for 27 to 45 consecutive days. The collections from men usually were pooled for three consecutive days. From the women we received two-day samples except during menstruation, when the excretions were pooled for the period. These urines were completely extracted, the androgenic and estrogenic activities separated from each other and assayed on capons and spayed rats respectively.

The results are given in tables 2, 3, and 4. In seven of the eight subjects we hydrolyzed the urine for two hours because at the time we had not discovered the importance of a brief period of hydrolysis. In subject 4, we limited the hydrolysis to 15 minutes, hence the greater yield of androgenic units in this individual. In both men and women we observe marked daily fluctuations in the urinary excretion of androgens and estrogens. The rates of excretion of the two activities bear no relation to each other.

Only one of the normal men gave an indication of a cycle in the rate of excretion of androgenic substances. Although the daily variations for a given individual and for the group of men are marked, the daily averages for the four individuals are remarkably constant, ranging from 63 to 68 international androgenic units. The averages for the estrogenic activity are also remarkably close, that is, 9 to 12 gamma theelin per day. By dividing the androgenic units per day by the gamma of theelin per day, we obtain

* These values are calculated on the assumption that the yield of androgenic activity is increased by 66 per cent over the 2-hour hydrolysis if boiled 15 minutes instead

what we call our An/Es ratios. This ratio ranges from 1 to 22 for the men, but when averaged again covers a relatively narrow range of 5.5 to 7.6

In the normal women the rate of excretion of androgens is also variable and of a high order, but distinctly lower than in men. The averages are again relatively constant as shown in table 4. The daily excretion of estrogens also varies considerably in normal women, but tends to be higher than in men. There is good evidence of the periodic rise and fall in the excre-

tion of estrogens in relation to the menses. The excretion of the estrogens generally is higher 7 to 14 days after the onset of menstruation and again 6 to 12 days before the next period. The excretion is lowest during menstruation. The An/Es ratios also vary tremendously in each of the four women, ranging from 0.3 to 11, but the averages range from 1.2 to 2.8 for women as compared with 5.5 to 7.6 for men (table 4). This change in ratio is due to the fall in excretion of androgens and rise in estrogens in women as compared with men.

In the present state of our knowledge we do not know how to explain these remarkable fluctuations. It is very probable that the exogenous source of these hormones is negligible because their presence in foods is limited to exceedingly small amounts and because their absorption probably is relatively difficult. Whether the endogenous source is limited to the gonads or whether the suprarenals and liver are also involved in the healthy individual, remains to be determined.

Studies in Hypogonadism. In two castrates we found 1 to 3.5 international capon units of androgens and 3 to 4.5 gamma theelin per liter of urine. These amounts may easily be of exogenous origin. In seven eunuchoids, the daily excretion varied from 5 to 19 international capon units of androgens and 1 to 9 gamma theelin per day. In two cryptorchids, the values were 9 to 31 and 1 to 6, respectively. Apparently there is no doubt that these extreme conditions lead to a very low excretion of both sex hormones. However, in spite of the low absolute excretion, the An/Es ratios ranged from 0.3 to 31.

Studies in Gynecomastia. In three cases of gynecomastia we found 0 to 37 androgenic units and 5 to 15 gamma theelin excreted per day. The An/Es ratios ranged from 0.1 to 2.5, but no excess excretion of estrogens was observed.

Studies in Virilism. In thirteen cases of virilism without obvious adrenal involvement, the daily excretion of androgens ranged from 5 to 55, of estrogens, from 4 to 19, resulting in ratios ranging from 0.2 to 7.5. In four cases with adrenal involvement, the androgen excretion values were 0, 44, 69, and 480 international units per day, and 4 to 8 gamma estrogens per day. The case with the highest value gave the An/Es ratio of 60. In general there appears to be a tendency to an increased An/Es ratio with a fall in excretion of estrogens in cases of virilism. This is, however, not always true. The patient with an excretion of 480 international androgenic units is of special interest for several reasons. First, because after removal of the adrenal cancer, the hirsutism disappeared, second, because absorption spectra studies indicate a possibly closer chemical relation of the androgenic substance to testosterone than to androsterone or dehydroandrosterone, and third, because studies by others on an oxidation product of a cortical adrenal hormone demonstrate its relation to testosterone chemically as well as biologically^{8,9}. This oxidation product was found to be one-sixth to one-

fourth as active as androstosterone in the capon. Others^{10, 11} have found exceedingly high concentrations of androgens in the urine from cases of adrenal tumors.

SUMMARY

1 There are marked daily fluctuations in the urinary excretion of androgens and estrogens in normal men and women.

2 The average daily excretion of androgens is 63 to 68 international units in men and 42 to 56 units in women.

3 The average daily excretion of estrogens, calculated as gamma of theelin, is 9 to 12 gamma for men and 18 to 36 gamma for women.

4 In male castrates, exceedingly small amounts of sex hormones are found in the urine.

5 In eunuchoids the excretions of sex hormones are distinctly lower than in normal individuals.

6 In gynecomastia, no excess excretion of estrogens was observed.

7 In virilism there is a tendency toward a lower excretion of estrogens with a normal or higher excretion of androgens.

8 In some cases of virilism with adrenal involvement, the excretion of androgens is exceedingly high.

MYXEDEMA, PRESENTATION OF A GROUP OF CASES ILLUSTRATING PHASES OF THE DISEASE WHICH ARE RECEIVING ATTENTION IN RECENT LITERATURE

By A. RAVIN, M.D., *Denver, Colorado*

RECENT investigations of myxedema have greatly increased our knowledge of the disease. Attention has been directed to newly recognized symptoms, to changes in the cholesterol and carbohydrate metabolism, and especially to the heart findings. The following case histories are presented because they illustrate these and other features of the disease. Since the cardiovascular changes in myxedema have been the object of so much discussion, they have been stressed in this article. A hypothesis to explain these changes on a pathological physiological basis is presented.

CASE REPORTS

Case 1 *Spontaneous myxedema in a woman aged 51, typical signs and symptoms, chronic valvular disease of heart in association with "myxedema heart", markedly dilated heart decreasing in size with thyroid therapy, increase in voltage in electrocardiogram with treatment, small maintenance dose of thyroid*

B. G., a white woman of 51, entered the clinic in January 1934 complaining of "shortness of breath," "lack of life," and "difficulty in hearing." One sister had diabetes and her father had had a cancer of the eyelid. Menopause occurred eight years ago. Her knees were stiff and swollen at 19 years of age. Patient believed that she was quite well until six or seven years ago. At that time she noticed that her eyelids became puffy, shortly afterwards her feet became edematous and recently her entire body, especially her abdomen, had begun to swell. She lacked energy. Memory was poor and she could neither think nor act rapidly. Her hearing had become poor and her voice husky in recent years. She could not stand cold weather. Her hands did not perspire. The skin had become dry and scaly. In spite of a poor appetite, weight had not been lost.

Examination revealed a small white woman who walked with a slow shuffling gait. She reacted slowly and talked slowly in a rather coarse, low-pitched voice. The skin was pale, dry, coarse and scaly. On each cheek was a small area of cyanosis. Hair was present only on the eyebrows, scalp, and pubis and in these regions it was scant, coarse, and brittle. The facial expression was dull and heavy. The cheeks were puffy and the lips thick. The thyroid could not be palpated. A few fine rales were heard at the bases of both lungs posteriorly. The blood pressure was 138 systolic and 102 diastolic. The pulse rate was 60 per minute with a regular rhythm. The heart was enlarged to percussion. A systolic murmur, most intense at the apex, was heard over the entire precordium. There was very little evidence of peripheral arteriosclerosis. The abdomen was distended but no shifting dullness was obtained. The liver was not palpated and was not down to percussion. A pitting edema of both legs was present.

The basal metabolic rate was minus 31, the blood cholesterol 300 mg. per 100 c.c.,

* Received for publication February 20, 1937.

From the Department of Medicine, University of Colorado School of Medicine.

the urine normal and the blood Wassermann test negative. The blood contained 3,470,000 red blood cells per cu mm and 9.8 grams of hemoglobin per 100 c c. The gastric analysis (test meal) showed no free hydrochloric acid and a total acidity of 8 degrees. The sugar tolerance curve (175 grams of glucose per kilogram body weight was given in all sugar tolerance tests) showed a somewhat diminished tolerance, the peak was at 192 in the first hour with a return to normal at three hours. All complexes in all leads of the electrocardiogram were of low voltage. Left axis deviation was present. The chest roentgen-ray (figure 1, A) revealed a bilaterally enlarged heart.

One-half grain of desiccated thyroid (Lilly's) was found to be sufficient to keep the basal metabolic rate within normal limits. Marked clinical improvement was evident shortly after starting treatment. The patient began to react more rapidly, walk more rapidly, and speak more rapidly. The puffiness gradually left her cheeks and eyes and the dull, myxedematous facies gave way to a more alert expression. The skin became more smooth and oily and hair began to grow more abundantly. Fatigue and weakness diminished. The edema of the extremities left. As the heart action became more vigorous, the systolic murmur remained and increased somewhat in intensity. This finding, combined with a history of "rheumatism" at the age of 19, made the diagnosis of rheumatic heart disease with mitral insufficiency very probable.

The remarkable changes which occurred in the size of the heart are illustrated in figure 1. On 4/12/34, the date of the last film, the basal metabolic rate was plus eight, the pulse rate 62 per minute, the blood pressure 135 systolic and 90 diastolic, the hemoglobin 12.8 grams per 100 c c and the red blood cell count 5,100,000 per cu mm. The electrocardiogram showed an increase in voltage of all complexes in all leads, the left axis deviation persisted. A gastric analysis still showed an achlorhydria with a total acidity of 10 degrees. A sugar tolerance on 5/27/34 revealed a peak of 220 in one hour with a return to normal in three hours.

Note (1) The very small dose of desiccated thyroid required to keep the basal metabolic rate at normal and produce the changes noted. (2) The remarkable decrease in heart size under thyroid therapy. (3) The low voltage in the electrocardiogram associated with the enlarged heart and the increase in voltage as the heart diminished in size under thyroid therapy. (4) The association of "myxedema heart" with a valvular lesion probably of rheumatic origin. (5) The family history of diabetes in a sister and the presence of a somewhat decreased sugar tolerance in the myxedematous state with a further decrease in tolerance after treatment.

Case 2 Spontaneous myxedema in a woman aged 31, typical signs and symptoms, including menorrhagia, variations in heart size with degree of hypothyroidism, association of rheumatic heart lesions and "myxedema heart"

M. S., a white woman, aged 31, entered the clinic on 3/24/31 complaining of extreme dyspnea on exertion and menorrhagia. About two years previous to her entrance she began to notice difficulty in breathing on exertion. She suffered constantly from extreme lassitude. In the last few years although her appetite had remained the same, she had gained 30 pounds in weight. She complained also of frequent headaches, occasional numbness of the right forearm and hand, painful and excessive menses, and sterility. The family history was essentially negative. Her husband had tuberculosis. There was no history of rheumatic fever, chorea, or frequent sore throats. Physical examination on admission showed an obese woman with puffy face and swollen eyelids, dry and scaly skin, and coarse hair. Blood

FIG 1 Case 1 (A) Before treatment BMR —31 Blood cholesterol 300 mg per 100 cc
 (B) One month after starting treatment BMR plus 3 Blood cholesterol 180 mg per 100 cc
 (C) Two months after starting treatment BMR plus 1
 (D) Three months after starting treatment BMR plus 8

pressure was 120 systolic and 80 diastolic Pulse rate 62 No murmurs were heard The basal metabolic rate was minus 30

Under thyroid therapy the patient improved marvelously In August 1932, however, she stopped coming to the clinic She continued to take thyroid for a number of months and then stopped In August 1934 she returned with very much the same story as on her first admission She felt weak, tired easily and had no

FIG 2 Case 2 (A) Two months before patient's first entrance into clinic BMR at time of admission into clinic was —30

(B) Patient had been taking thyroid for over one and a half years BMR —10 It must be noted in comparing the plates that although in the other three plates the diaphragm is almost at identical levels, in this plate it is slightly lower

(D) After about four weeks of thyroid therapy BMR —14

energy. Her entire body seemed, to her, to be more or less swollen. Her skin had recently become coarse and her finger nails brittle. Examination revealed most of the signs of myxedema: slow response, dry, coarse skin, puffy cheeks and swollen eyelids. The heart was enlarged to percussion. No murmurs were heard. The basal metabolic rate was minus 34 and blood cholesterol 236 mg per 100 c c. The sugar tolerance curve was normal. Electrocardiogram revealed a low voltage of all complexes.

FIG 3 Electrocardiographs taken on Case 2. Upper tracing on 9-1-34 before thyroid therapy. Lower tracing on 9-27-34 after about four weeks of treatment.

Four weeks after starting thyroid therapy (final maintenance dose was three grains of desiccated thyroid daily) the patient showed the usual signs of improvement. Examination of the heart at this time showed it to be normal in size. Very definite mid-diastolic, presystolic, and systolic murmurs were heard and the diagnosis of mitral stenosis and insufficiency was beyond question. These murmurs were not heard before treatment in spite of several careful examinations. The interesting changes which occurred in the size of the heart are illustrated in figure 2. The electrocardiogram showed increased voltage throughout (figure 3). A sugar tolerance taken eight months after starting treatment was normal. A blood cholesterol at the same time was 137 mg per 100 c c.

Note (1) Variations in heart size corresponding to degree of hypothyroidism. (2) Association of "myxedema heart" and rheumatic heart lesions. (3) Menorrhagia, which is referred to as of frequent occurrence.

in myxedema (4) Absence of the characteristic murmurs of mitral stenosis and insufficiency in the hypothyroid state Several factors are probably involved Most important is probably the decrease in velocity of blood flow The diastolic murmurs of mitral stenosis will sometimes disappear when auricular fibrillation sets in, and the explanation usually given is that the absence of murmurs results from the decrease in velocity of blood flow The conditions appear analogous The increased viscosity of the blood in myxedema may hinder the production of murmurs The possibility of dilated rings in a dilated heart must be considered

Case 3 Spontaneous myxedema in a 16 year old girl, typical signs and symptoms, heart size within normal limits before treatment with decrease in size after treatment, abnormal electrocardiographic features with change to normal after thyroid therapy

S. C., a white girl, aged 16, entered the clinic on 1/15/34 with a history of being tired and cold all the time, having no appetite, swelling of the feet, and infrequent menses Symptoms had been present for the last five years and during that time she had been told by a private physician that she had heart and kidney trouble and had been in a hospital with a diagnosis of cardio-renal disease Physical examination revealed enough of the signs of myxedema to make the diagnosis quite evident—mental retardation, pale, dry skin, dull facies, marked supraclavicular pads of fat (figure 4) and slow pulse The heart was apparently normal in size with a transverse diameter of 10.3 cm There was no edema of the extremities The basal metabolic rate was minus 41, blood cholesterol 350 mg per 100 cc, fasting blood sugar was 64 mg per 100 cc The electrocardiogram revealed flat T-waves in all leads, right axis deviation, and a QRS spread of 0.12 second The patient showed the usual

FIG 4 Case 3 (A) Taken on 1-12-34 before starting thyroid therapy (B) Taken on 5-28-34 after about five months of treatment Note loss of the supraclavicular pad of fat

marked and gratifying improvement with thyroid. The transverse diameter of the heart decreased to 9.6 cm. The electrocardiogram now showed T-waves of good voltage in all leads, normal axis deviation, and a QRS spread of 0.08 second.

Note (1) Change in heart size even though the heart was apparently normal in size before treatment. (2) Marked electrocardiographic changes with a heart of apparently normal size. (3) The erroneous diagnosis of renal, or cardio-renal disease, not infrequently made in these cases.

Case 4 Postoperative myxedema in a woman aged 27, mental reactivity out of proportion to myxedematous state, abnormal electrocardiograph with heart of normal size, marked anemia responding only to non administration, prolonged tendon reflexes

J. B., a white woman, aged 27, entered the clinic on 11/27/34 complaining of "nervousness and palpitation" of several years' duration. In 1928 she noticed some enlargement of her neck, her nervousness and palpitation began about the same time. The next year exophthalmus, more prominent on the left, appeared. In July 1933 the diagnosis of toxic goiter was made and a thyroidectomy performed. This resulted in a temporary improvement of the symptoms but the nervousness and palpitation soon returned. On entrance into the clinic she complained also of being very weak and tiring easily. Although her appetite was poor, it was significant that she had not been losing weight. For several months a puffiness of the face and eyes had been noticed. She was sensitive to cold and her skin had become dry and coarse. Menstruation had begun at 14 and had been regular and normal until the toxic goiter developed, when the flow became excessive, after thyroidectomy, the flow became normal.

Patient was very talkative and spoke rather rapidly. She thought and responded with normal or increased rapidity. In general, her behavior corresponded more with that of a hyperthyroid than a hypothyroid individual. The facies presented a peculiar combination of the residue of hyperthyroidism (exophthalmus) and the features of hypothyroidism (puffy cheeks and eyelids, pasty skin). The skin was pale, dry and scaly. The blood pressure was 100 systolic and 76 diastolic. Pulse rate was 70 per minute and regular. Heart sounds were faint. There was no evidence of peripheral edema. Reflexes showed the prolonged contraction considered by Chaney¹² as pathognomonic of myxedema.

The basal metabolic rate was minus 30, the blood cholesterol 310 mg per 100 c.c., the urine normal, and the blood Wassermann test negative. The blood contained 3,270,000 red blood cells per cu. mm. and 8.8 grams of hemoglobin per 100 c.c. The sugar tolerance curve was normal, possibly slightly high, as the peak was at 176. Roentgen-ray showed the heart to be of normal size and appearance. The electrocardiogram revealed a low voltage of all complexes in all leads, the T-wave in Lead II was iso-electric.

Desiccated thyroid, one-half grain daily, was started and the dose was gradually increased to two grains daily. On this dose the basal metabolic rate became and remained normal (minus 7 to plus 9) and the blood cholesterol fell to 173 mg per 100 c.c. The heart showed no significant change in size. The voltage of the T-wave in Lead II became one mm. and the voltage of the other complexes increased slightly. The change in the patient's condition was the remarkable one usually seen in these cases, she felt well and had very few complaints. On 4/4/35, five months after starting thyroid therapy, the hemoglobin was still 8.8 grams per 100 c.c. in spite of the improvement in the other signs and symptoms. Iron by mouth was started and on 6/7/35 the hemoglobin had increased to 13.7 grams per 100 c.c. Figure 5 shows the change in the Achilles tendon reflex which occurred under treatment.

FIG 5 Case 4 Prolongation of the Achilles reflex in the myxedematous state (B) and shortening after thyroid therapy (C) A normal record (A) is presented for comparison

Note (1) The presence of a mental activity such as one might expect in hyperthyroidism persisting after the physical and laboratory signs of myxedema had developed. It is, of course, probable that the patient was mentally retarded in comparison to her previous hyperthyroid state, she still showed, however, a mental reactivity out of all proportion to her hypothyroid state. (2) The presence of low voltage in the electrocardiogram with a heart of normal size. (3) The most notable change in the electrocardiogram after therapy was increase in the voltage of the T-wave in Lead II. (4) The failure of the rather marked anemia to respond to thyroid therapy and the good response when iron was given. (5) The presence of the prolonged reflex as noted especially in the Achilles tendon reflex.

Case 5 Spontaneous myxedema in a woman, aged 51, with an interesting family history of diabetes

M. M., a white woman, aged 51, entered the clinic on 12/18/34 with numerous complaints, including the usual ones of fatigue, shortness of breath, inability to tolerate cold, poor appetite, constipation and slow mentation. Examination revealed the common signs of myxedema. The basal metabolic rate was minus 38, the blood cholesterol 283 mg per 100 c.c., the blood Wassermann test negative. Urine was normal except for a small number of pus cells. The blood count showed 3,800,000 red blood cells per cu. mm. and 12.5 grams of hemoglobin per 100 c.c. The sugar tolerance curve was normal. The gastric test meal showed no free hydrochloric acid and a total acidity of eight degrees. Roentgen-ray revealed a normal sized heart. In the electrocardiogram inverted T-waves in all leads, low voltage, and a slight left axis deviation were present.

Three grains of desiccated thyroid daily were required to keep the basal metabolic rate within normal limits. Laboratory tests six months after starting treatment were as follows: Red blood count 4,250,000 cells per cu. mm., hemoglobin 14.5 grams per 100 c.c., blood cholesterol 167 mg per 100 c.c., sugar tolerance normal—the curve was somewhat flatter than before treatment, gastric test meal unchanged. Heart size was unchanged. The electrocardiogram had become normal with an increase in voltage of the QRS complexes, upright T-waves in all leads, and no axis deviation.

Of special interest in this case is the family history. A sister died of diabetes. A son died in diabetic coma. A daughter has diabetes and congenital heart disease.

DISCUSSION

Terminology The term myxedema was applied by Ord,¹ in 1880, to the syndrome of "adult cretinism." As is common in other diseases, the outstanding or unusual characteristic of the disease was used as a name for the entire condition. When we speak, therefore, of an individual having myxedema, we refer to the entire syndrome—the slowed mental and physical processes, the dry skin, the brittle nails, the elevated blood cholesterol, the changed protein and mineral metabolism, and the other recognized changes—not to the single feature of myxedematous infiltration of the tissues. Since decrease or absence of thyroid secretion produces the state of myxedema in all of its features, we must consider myxedema as a manifestation of diminished thyroid secretion. Hypothyroidism, and myxedema are, therefore, synonymous terms. To speak of hypothyroidism without myx-

edema, as is occasionally done, is incorrect unless the term myxedema is used in its restricted sense, in which case one could also speak of myxedema without myxedema, using the term first as the name of a clinical entity and then as a description of a specific pathological condition. The expression "hypothyroidism without myxedema" is usually misused in reference to mild cases of myxedema, or, more frequently, to cases of hypometabolism. Myxedema and hypothyroidism imply more than hypometabolism and should not be used in the absence of other evidences of diminished thyroid function.

Symptomatology When it is recalled that the symptoms of myxedema are all produced by the absence of one hormone and entirely alleviated when that hormone is replaced, it is not surprising that a striking similarity is usually noted in the histories of cases of myxedema. Variations are to be expected in degree rather than in kind. Furthermore, it is unlikely that one symptom or sign would occur without the others being present in about equal degree. If, as recent experience indicates, normal cholesterol metabolism is closely dependent on the presence of a normal amount of thyroxin, we would not expect a markedly lowered basal metabolic rate due to lack of thyroxin without some evidence of altered cholesterol metabolism. The same reasoning applies to the other changes. The occasionally noted variations from this conclusion may possibly be explained in three ways. First, our normal standards for any one sign or symptom are averages from which marked variations must occur and what may, therefore, appear to be normal by our standards may really be abnormal for a specific individual, or vice versa. Second, it is possible that variation may occur at times in the susceptibility of a certain tissue to thyroxin, the tissue may develop an increased sensitivity or an increased refractility to thyroxin. Third, one or more of the signs of diminished thyroid secretion may be concealed by the presence of another pathological condition affecting the same signs in an opposite manner.

Means and Richardson² print a table compiled by Krantz showing the incidence of various signs and symptoms, table 1 is in great part derived from that table and shows in outline those symptoms which occur in the majority of cases. Experience indicates that the symptoms of myxedema develop slowly over a period of months and years. Menorrhagia is frequently seen in women in whom myxedema occurs before menopause.³ M. S. (Case 2) had two uterine curettements with little relief for a symptom that responded readily to thyroid therapy. J. B. (Case 4) illustrates a condition occasionally seen in patients with postoperative myxedema. Although most of the signs and symptoms of myxedema were present—lowered basal metabolic rate, elevated blood cholesterol, dry pasty skin, inability to stand cold, and fatigue—the mental processes were not slowed and were, indeed, more of the type which one might expect with her previous state of exophthalmic goiter. Thyroid medication produced marked improvement. Since her reactivity had always been normal or increased, very little change was noted in this feature, one did, however, feel that her speech and actions were more relevant and consistent than they had been previously.

TABLE I
Myxedema
Symptoms and Findings

| | | | |
|----------------------------------|--|-------------------------------------|--|
| <i>General</i> | | <i>Edema</i> | |
| (1) Fatigue | | (1) Eyelids | |
| (2) Weakness | | (2) Face—checks | |
| (3) Inability to stand cold | | (3) Ankles | |
| (4) Weight increase | | Non-pitting | |
| (5) Fat increase | | Pitting | |
| General | | <i>Mental and Neurological</i> | |
| Supraclavicular | | (1) Drowsiness | |
| <i>Skin</i> | | (2) Slow speech | |
| (1) Paleness | | (3) Numbness and tingling | |
| (2) Dryness and scalliness | | (4) Impairment of memory | |
| (3) Absence of sweating | | (5) Impairment of hearing | |
| (4) Hair—Scanty | | (6) Prolongation of tendon reflexes | |
| Coarse | | <i>Gastrointestinal</i> | |
| (5) Nails brittle | | (1) Constipation | |
| <i>Circulatory</i> | | (2) Poor appetite | |
| (1) Shortness of breath | | (3) Indigestion | |
| (2) Slow pulse | | <i>Blood</i> | |
| (3) Small pulse pressure | | (1) Increased cholesterol | |
| (4) Poor quality of heart sounds | | (2) Moderate anemia | |
| (5) Dilation of heart | | <i>Lowered Basal Metabolic Rate</i> | |
| (6) Electrocardiographic changes | | | |
| Low voltage, especially in T- | | | |
| waves in Leads I and II | | | |

Perhaps in this case the nervous system had been so sensitized that it responded to smaller amounts of thyroxin than the other tissues

The presence of "circumscribed myxedema" in cases of hyperthyroidism has recently been receiving some attention⁴ and presents an interesting paradox. Perhaps the explanation is in terms of development of decreased sensitivity to thyroxin in a limited area.

Basal Metabolic Rate The lowered basal metabolic rate is certainly of great importance in the diagnosis of myxedema. It must be emphasized, however, that a low basal metabolic rate is not of itself an absolute indication that hypothyroidism is present. Many individuals have a basal metabolic rate well within the myxedema range and have no myxedema. The low rate may represent their normal, or some factor other than lack of thyroxin may cause the lowered metabolism.

When the basal metabolic rate falls below minus 20, patients with myxedema usually begin to show mild symptoms—sensitivity to cold, dryness of skin, absence of sweating, but they do not develop the marked symptoms—swelling, mental retardation, cardiovascular changes—until the basal metabolic rate has been below minus 30 for some time.³ The question of whether symptoms of myxedema can occur with a normal basal metabolic rate is often raised. Patients are occasionally seen who have normal basal metabolic rates and who present symptoms which might be of myxedematous origin and which appear to respond to thyroid. One such case was seen recently in which there was also a somewhat elevated blood cholesterol. When we recall that the basal metabolic rate is influenced by factors other

than thyroid, the possibility of a myxedematous individual with a normal basal metabolic rate would appear to exist. Those cases in which the basal metabolic rate is elevated because true basal conditions were not obtained during the test do not belong in this category but should not be forgotten. An individual whose normal basal metabolic rate is plus 20 or more might show signs of hypothyroidism with a normal basal metabolic rate. A myxedematous individual taking dinitro-ortho-cresol⁵ would be an excellent example of a case of myxedema with a normal or even elevated basal metabolic rate. Whether cases might exist in which some substance similar to dinitro-ortho-cresol would be produced spontaneously in an individual having myxedema, thus fulfilling the above conditions, remains for the future to decide.

Blood Cholesterol Although it has long been known that changes in cholesterol metabolism are associated with thyroid dysfunction, the importance of these changes has only been recognized in recent years. Investigations have shown that the blood cholesterol is usually diminished in hyperthyroidism and almost invariably elevated in hypothyroidism. So consistent is this elevation of the blood cholesterol in myxedema that it has been suggested that the three criteria for the diagnosis of myxedema be (1) the presence of the characteristic symptoms and physical findings, (2) a lowered basal metabolic rate, and (3) an elevated blood cholesterol. To these might be added a fourth, return of the above three to normal under thyroid therapy. It has been pointed out that the efficacy of treatment can usually be predicted on the basis of whether or not the blood cholesterol is elevated. Those cases which have low basal metabolic rates and no signs of myxedema rarely show elevated blood cholesterol and are rarely benefited by thyroid therapy. Hurxthal⁶ believes that the finding of hypercholesteremia, in the absence of its few other common causes, points more specifically to thyroid deficiency than does the finding of a low metabolic rate. Determination of blood cholesterol has attained such importance that it may be said that no report of a case of hypothyroidism is complete unless the blood cholesterol value is given. It is interesting to note that in Case 2 the blood cholesterol before treatment, 236 mg per 100 c c, might possibly have been considered a high normal. After treatment, however, it fell to 137 mg per 100 c c, showing that the initial value represented an increase of more than 70 per cent over the normal value and again emphasizing the importance of variations in normal as an explanation of unexpected findings.

Recent studies of creatinuria in children with hypothyroidism require comment. Until about the age of puberty creatine is normally found in the urine of children of both sexes. In hypothyroidism in children the creatine excretion may diminish or cease entirely. With proper administration of thyroid creatine again appears in the urine.⁷

Carbohydrate Metabolism A consistent feature of experimental and clinical studies on carbohydrate metabolism is the lack of agreement between

the results of various workers. Several factors probably account for this poorly controlled experiments, conclusions drawn from too small a number of experiments, and the presence of only a small correlation between the two conditions. The conclusion that in myxedema the tolerance for carbohydrate is increased appears to be commonly accepted in recent literature but cannot be drawn with assurance from the results of experiments on animals ^{8,9}. The same is true of work on patients with myxedema without any evidence of diabetes, low blood sugars, normal blood sugars, low prolonged sugar tolerance curves, high prolonged sugar tolerance curves, and other types of curves have been reported. A glaring fault in many of these reports is the small number of cases. Some recent well controlled experiments ¹⁰ on hypothyroidism induced by total thyroidectomy indicate that carbohydrate metabolism is not significantly influenced by the hypothyroidism following total thyroidectomy. The belief that the tolerance for carbohydrate is increased in myxedema would appear to rest on two factors: first, it is well recognized that the sugar tolerance is diminished in hyperthyroidism and one would expect it to be increased in hypothyroidism, second, rather definite evidence exists that when diabetes mellitus and myxedema occur in the same individual, the diabetes becomes more severe as the myxedema is treated. It is believed that the decreased severity of the diabetes in myxedema results from the lowered metabolism and does not indicate any antagonism between the secretions of the thyroid and the pancreas. The lack of agreement concerning the effect of hypothyroidism on patients without evidence of diabetes, and the general agreement concerning the mitigating effects of hypothyroidism on diabetes may possibly be correlated as follows. The effect of hypothyroidism, or possibly lowered basal metabolic rate only, is not great enough to be detected by a rather crude test such as the sugar tolerance test because of the great reserve present in the carbohydrate metabolism. When, however, this reserve is lost, as in diabetes, the effect becomes evident.

Shepardson and Wever ¹¹ came to the conclusion, from a review of the literature "that the coincidence of diabetes mellitus and myxedema is probably no more nor less common than could be predicted from the occurrence of the two diseases separately." They also concluded that only 13 cases of diabetes combined with myxedema have been reported in literature. The actual number must be much greater. The family history of diabetes in two of the above cases (Cases 1 and 5) is very interesting. Case 1 is the only one that presented an abnormal sugar tolerance curve. She showed diminished tolerance which was somewhat further diminished by thyroid therapy but not beyond the limits of error of the test.

Change in Reflexes In 1924 Chaney ¹² described the abnormally prolonged character of the tendon reflexes in myxedema. On striking the tendon, the muscle contracts about as rapidly as normally, but remains contracted for as long as a second and relaxes slowly. Chaney apparently

obtained this prolongation in all of his cases of myxedema and considered it to be specific for myxedema since it did not occur in other conditions associated with lowered basal metabolic rates. Although this prolongation of the reflex is very striking and characteristic, it certainly is not always present. Case 1 did not show it or at least did not show it to an extent to be clinically observable. Case 3 showed it at times and at other times gave a quite rapid and normal reflex. When the prolonged reflex is present, it returns to normal with the basal metabolic rate. Figure 5 shows the nature of the reflex as obtained in Case 4 and the improvement with therapy. The prolonged reflex is an interesting sign which may, at times, be of help in diagnosis, but too much importance must not be attributed to its absence.

Blood and Urine The moderate degree of anemia which occurs in most cases of myxedema has been attributed to the diminished activity which the blood forming tissues share with all the other tissues. It must be remembered, however, that the pastiness of the skin in myxedema is out of all proportion to the degree of anemia, which may be very mild. Some improvement of the blood count and hemoglobin occurs with thyroid treatment but it has been my experience that iron therapy must often be used to bring the blood up to a full normal. In spite of remarkable improvement in all other ways in Case 4, a fairly marked anemia did not respond to thyroid but responded almost immediately to iron.

The urine is usually normal and was so in all of the above cases. However, traces of albumin do occur at times and are of interest only from the standpoint of diagnosis since, as in Case 3, these patients are frequently diagnosed as nephritics.

Gastric Acidity In spite of some observations to the contrary, the bulk of evidence appears to indicate that there is a definite decrease in gastric acidity in both hyperthyroidism and myxedema.¹³ Even more definite is the increase in incidence of achlorhydria in myxedema and a few observations¹⁴ indicate that this achlorhydria is not influenced by treatment (Cases 1 and 5). Interpretation of these findings, should further study confirm them, is difficult.

Cardiovascular Changes Zondek¹⁵ in 1918 used the term "myxedema heart" to describe a condition found in some cases of myxedema and characterized by an enlarged heart, sluggish cardiac movements and certain electrocardiographic changes. Although "myxedema heart" was at first thought to occur only rarely, recent literature contains ample evidence that it is a common and possibly the usual finding in myxedema. Lerman, Clark and Means¹⁶ believe that "the heart is generally enlarged in myxedema." The incidence of recognition of cardiac enlargement increases with greater care in examination and more frequent use of roentgen-rays. The enlargement, at times quite marked (Case 1), usually involves both sides of the heart. Digitalis has very little influence on the size of the heart, but thyroid therapy decreases the size. The changes which occurred in Case 1 are

shown in figure 1, the small amount of thyroid given in this case (one-half grain daily) is noteworthy. In some cases the heart will decrease in size after thyroid therapy even though it was apparently normal in size before treatment (Case 3). If thyroid is stopped, the heart enlarges, it shrinks again on resumption of thyroid (Case 2, figure 2).

Does the increased heart shadow mean hypertrophy, dilatation, or increased pericardial fluid? The rapid and, in many cases, great decrease in heart size appears to rule out hypertrophy as the entire explanation. Interstitial and intracellular edema, described below, might increase the size somewhat but hardly enough to account for the extent of enlargement which occurs in many cases. Reports of myxedematous patients showing pericardial effusion^{17, 18} and especially a case to be reported by Wang, emphasize the part which pericardial effusion may play in some cases. Lerman, Clark and Means¹⁹ feel that "in most cases, however, neither the clinical findings nor the roentgen-ray picture of the heart are consistent with significant amounts of pericardial fluid." We must conclude then that the increase in heart shadow is usually due to cardiac dilatation.

In spite of several earlier reports to the contrary, recent studies indicate that patients with myxedema almost invariably show typical abnormalities in the electrocardiogram and that these changes are favorably influenced by thyroid therapy. They occur even when cardiac enlargement is not present (Cases 4 and 5) and may be considered as early evidences of those alterations in the heart muscle which later may produce dilatation. Flattening or inversion of the T-wave in Lead II is considered the most characteristic change, but flattening of the other T-waves and general low voltage of all complexes in all leads also usually occur. Various other findings have been reported but not as constantly as the above. Many of these changes are illustrated in the cases here reported, all of which showed definite deviations from the normal in the electrocardiogram. These abnormalities usually disappear under thyroid treatment.

If we look for an explanation of the dilatation of the heart, we find that the cardiovascular changes which occur in myxedema can, for the most part, be divided into two groups: (1) those diminishing the circulatory load, and (2) those diminishing the strength of the cardiac contraction. In the former group belong the decreased blood volume and cardiac output. In the latter belong the pathological changes in the heart and blood vessels, the diminished coronary circulation and, possibly, the loss of the tonic effect of thyroxin on the heart muscle. The mild anemia which is often present would be another factor decreasing the cardiac efficiency.

The cardiac minute volume output is markedly diminished in hypothyroidism¹⁹ in the absence of cardiac insufficiency. Of major importance in producing this diminished cardiac output is the decreased blood volume.^{20, 21} Thompson²⁰ calculated that the increase in total blood volume on administration of thyroid to cases of myxedema was not infrequently as

much as 25 per cent. The relationship between the cardiac output and the blood volume is evident in the observation that other conditions remaining the same, the cardiac output varies directly with the volume of circulating blood ²². As pointed out below other factors are probably also involved in the production of the diminished cardiac output.

Of the factors decreasing cardiac efficiency, the pathological changes in the heart muscle must be most important. Exact information is lacking concerning the nature of these changes because of the dearth of autopsy material on untreated cases and because of our inability to distinguish between those changes due to myxedema and those due to commonly associated conditions most important of which is arteriosclerosis. Experimental work in animals must be interpreted with caution. Changes due to myxedema can be divided into those that are reversible, that is, disappear on giving thyroid, and those that are irreversible. Possible reversible changes in the myocardium are (a) interstitial edema, (b) intracellular edema, and (c) a moderate degree of granular degeneration. Among the irreversible changes is the degeneration of the muscle fibers described by Webster and Cooke ²³ and others. The changes produced by such complicating factors as arteriosclerosis and hypertension and exemplified by coronary sclerosis and myocardial fibrosis are of course irreversible.

Although it appears to be generally assumed that the coronary blood flow in myxedema is decreased, attempts to analyze the possible changes in the light of modern conceptions of the mechanics of coronary flow would seem inconclusive. In a denervated heart preparation, the mean pressure in the aorta appears to be the most important factor determining coronary blood flow ²⁴. Since in myxedema the diastolic pressure is usually increased and the systolic pressure very often somewhat increased, if blood pressure were the only factor, coronary blood flow might also be increased. In the intact heart preparation, however, a reflex nervous mechanism apparently keeps the coronary blood flow proportional to the cardiac output ²⁴. Since the cardiac output is greatly decreased in myxedema, a diminished coronary flow is to be expected. The influence of other factors, such as, rate and strength of contraction, and muscular tone cannot be properly measured in our present state of knowledge. Essex and his co-workers ²⁵ state that thyroxin augments the coronary flow as much as 300 to 400 per cent over the control values. The extent of the increase is so great that it would appear that some specific effect might be involved. Since decrease in cardiac output is the most marked change and since this decreases coronary flow it is probable that the final effect is a diminished coronary blood flow.

Yater ²⁶ and others have shown that thyroxin stimulates the heart muscle producing an increase in heart rate. It is quite possible, although not proved, that it may also exert a tonic action on the heart. Yater advances the hypothesis that the increased circulatory output in hyperthyroidism is not a result of the increased need of the tissues for oxygen but a fortuitous

circumstance resulting from the stimulation of the heart by thyroxin. Without entering upon a critical analysis of the theory, we may advance the corollary in regard to myxedema. The diminished circulation in myxedema would thus be considered, not as an adjustment of the circulation to a diminished oxygen need, but a fortuitous condition arising from the lack of thyroxin to stimulate the heart. The decreased blood volume, described above, and the poor venous return resulting from the diminished muscular activity and lowered skeletal muscle tone would further lower the cardiac output. In favor of this hypothesis is the lack of correlation between the lowered basal metabolic rate and the decrease in cardiac output¹⁰; the cardiac output is decreased more than would be expected and an increase in the arterio-venous oxygen difference is produced.

The incidence of hypertension seems to be greater in patients with myxedema than in the general population^{16, 17}. On treatment the fall of blood pressure in those patients showing hypertension is apt to be marked and in a large proportion it returns to normal. Occasionally a patient showing a normal blood pressure before treatment may become hypertensive under thyroid therapy. Although hypertension when present means an added load on the heart, the possibility that it may represent a compensatory mechanism must not be forgotten.

Having examined the changes which increase and also those which decrease the load of the heart, we may follow Hallock²⁸ in his explanation of the dilatation of the heart. The pathological changes in the muscle, the diminished coronary circulation, the loss of the tonic action of the thyroxin, and the mild anemia tend to diminish the strength of the cardiac contraction—to make the heart hypotonic. Although the diminished blood volume and circulatory output decrease the work of the heart, in some cases they do not balance the harmful factors and the heart cannot carry on its work without in some way increasing the strength of its contractions. This it can do by increasing its diastolic size since according to Starling's "law of the heart" the greater the initial length of the muscle fibers, that is, the greater the diastolic size of the heart, the greater the force of contraction. The heart, therefore, increases its diastolic size.

We must leave Hallock at this point to consider another phase of the problem, the relation of venous pressure to cardiac dilatation. Increased venous pressure is the price that the heart usually pays for the increase in size which permits it to contract more strongly. This will be made more evident if we examine Harrison's concept of the cause of increased venous pressure in the pulmonary circuit²⁹. If the left ventricle is working against a load (or if, for any reason, it cannot contract as efficiently as previously) it does not expell the usual quantity of blood. Since it is still receiving the same amount, the blood collects in the ventricle and its diastolic size increases. With increase in size, its strength of contraction increases and it now expells its original amount. As the left ventricle dilates, however,

the pressure in it rises a little toward the end of diastole and the left auricle, now working against this greater pressure, fails to empty itself completely and blood collects in it until, in spite of its distensibility, the pressure increases. As a result of this increase in pressure in the auricle, less blood enters the auricle than formerly. Since the right ventricle is still expelling the same amount, the blood accumulates in the lungs and the pressure in the pulmonary circuit increases. This rise in pressure now corresponds in degree to the increase in the pressure in the left auricle. It can thus be seen that the origin of the increase in venous pressure in the pulmonary circuit (pulmonary congestion) is in the resistance of the muscle fibers of the left ventricle to stretching. If in the foregoing illustration the muscle fibers of the ventricle could have stretched without requiring an increase in the pressure in the ventricle toward the end of diastole, there would have been no need for increase in pressure in the auricle and no resulting pulmonary congestion. The factor involved might thus be considered a sort of "stretching resistance" of the muscle fibers, or a "filling resistance" of the heart. This resistance to stretching may depend upon a sustained partial contraction of the fibers (muscle tonus) or upon the elastic properties of the fibers and would vary with changes in either. Because of this "filling resistance," dilated hearts, beyond a certain degree, are ordinarily accompanied by signs of congestion, that is, signs of increased pulmonary or systemic venous pressure. If, then, the "filling resistance" is normal in myxedema we would expect to find congestive signs with moderately or greatly dilated hearts.

Congestion in the pulmonary system would be evidenced by diminished vital capacity, dyspnea, orthopnea, increased pulmonic second sound, basal râles, and cough. Vital capacity studies have not as yet been complete enough to give definite evidence for or against the presence of congestive failure in most cases. The observation²¹ that the vital capacity was strikingly diminished in myxedema in the absence of any signs of congestive heart failure, and did not show significant changes following treatment makes any interpretation of vital capacity studies difficult. Dyspnea is one of the earliest evidences of congestive failure but as it can be produced by other causes it cannot by itself be considered as absolute evidence of congestive failure. Its frequency in myxedema may be otherwise explained. Of primary consideration is the patient's frequent confusion of shortness of breath and fatigue. The latter is a marked and universal symptom in myxedema and close questioning will often reveal that what was considered shortness of breath is really fatigue. With diminished blood volume, and with inadequate venous return as a result of poor muscle tone and diminished and poor contraction of the skeletal musculature, it is possible to have dyspnea on the basis of inability to increase cardiac output from a form of peripheral failure. Orthopnea is only rarely described as a symptom in myxedema. The pulmonic second has not been mentioned as accentuated

Basal râles and cough are occasionally present but usually no more frequently than might be expected from causes other than congestive failure.

Evidences of increased systemic venous pressure are indicated by distended cervical veins, increased venous pressure measurements, peripheral edema, and enlarged liver. Distended cervical veins are only occasionally noted in the literature. They were not seen in Cases 1 and 2 above. Where reports of venous pressure measurements are mentioned they have usually been normal. The work has, however, been done in most cases on patients with normal sized hearts and with no signs of venous congestion. Altschule and Volk¹⁹ found that the venous pressure remained normal in three cases of postoperative myxedema in which the heart enlarged with development of the hypothyroid state. Pitting edema around the ankles occurs in a large percentage of the cases of myxedema including many cases with hearts of normal size. Since edema on a cardiac basis does not occur, with rare exceptions, unless the heart is dilated, we must assume that in most cases of myxedema the edema is on a non-cardiac basis. Edema, when present, may be on the basis of local circulatory changes such as poor venous return due to poor muscle contraction and tone, on interference with venous return due to fatty and possibly myxedematous deposits, and on local tissue changes. The presence of an enlarged liver which diminishes in size after treatment is occasionally reported.

It can thus be seen that in only a small percentage of the cases of myxedema with cardiac enlargement can the signs and symptoms be considered as conclusive evidence for the presence of congestive heart failure and that in most cases one need not assume the presence of congestive failure. We have then a condition in which the heart is dilated, often greatly, and it has done so without paying the price of increased venous pressure, in other words, the "filling resistance" is decreased. This may possibly result from a loss of the tonic effect of thyroxin or from changes in the elastic properties of the muscle fibers produced by the absence of thyroxin. Even more definite evidence of this decrease in the "filling resistance" may be found in cases of congestive failure treated by total ablation of the thyroid. In some of these cases improvement, decrease or clearing up of the symptoms of congestive failure, may occur even though the heart continues to dilate³⁰ that is, the same or a greater degree of dilatation may be present with a lower venous pressure. The improvement in these cases is usually ascribed to the diminished demand on the heart which results from the lowered metabolism. Although the importance of this factor is evident, it does not explain how the heart can maintain the same size or even become larger while the venous pressure decreases. The heart in these cases must have less "filling resistance," permitting dilatation with a smaller venous pressure. If by the induction of hypothyroidism in these cases of circulatory failure, the circulatory load is diminished and the heart permitted to maintain its same size with a lower venous pressure (thus giving it the advantage of increased

diastolic length), and if the pathological changes resulting from hypothyroidism are kept at a minimum by not permitting too low a basal metabolic rate, the improvement often seen can easily be explained.

The foregoing discussion may be summarized as follows. The changes in the heart produced by lack of thyroid tend to make the heart hypotonic. At the same time changes occur in the muscle fibers which permit them to stretch more easily and give the heart a diminished "filling resistance." If the hypotonicity is great enough to require a greater initial length of the muscle fibers to produce an adequate contraction, the heart dilates, but since the "filling resistance" is diminished it does so without increase in venous pressure and without congestive changes. If pathological changes, such as arteriosclerosis, hypertension, or rheumatic heart disease are present, congestive failure may occur either because the dilatation is sufficient to produce increased venous pressure in spite of the lower "filling resistance," or because the "filling resistance" cannot diminish as much in an hypertrophied or fibrotic heart as it does in a normal heart.

On treatment with thyroid, various results might be expected. If the pathological changes are reversible, the heart size may decrease as a result of the improvement in tonus. If the pathological changes cannot be reversed by thyroid, the individual may become worse since the "filling resistance" and the circulatory load are increased, congestive failure may result or become aggravated. In some cases the factors may balance and the condition remain the same.

TREATMENT

Many cases of myxedema are quite sensitive to thyroid and only small doses are needed to produce marked changes. This is very nicely illustrated in Case 1. It has been said that the more thyroid an individual can tolerate, the less hypothyroid he is. In view of the marked cardiac changes which are frequently present, the necessity of increasing the basal metabolic rate gradually and permitting the heart to adjust itself to the changed load is obvious.

Various brands of thyroid contain different amounts of iodine and show some variation in strength. Furthermore, some firms label tablets according to the amount of fresh gland present and others according to the amount of dried gland present. Since one part of dried gland is equivalent to about five parts of fresh gland, this difference must be remembered, for example, a five grain B. W. and Co. tablet is approximately equal to a one grain Lilly tablet.

Finally, since "the effects (of thyroxin) start only a day after administration, even with intravenous injection, and then continue to increase, reaching their maximum in about 10 days, after a single dose,³¹" it is useless to give thyroid in broken doses during the day.

INFANTILE CEREBRAL PALSY, ITS TREATMENT BY SELECTIVE INHIBITION OF SENSORY STIMULI

By EARL R. CARLSON, M.D., *New York, New York*

WHEN the nervous system has been damaged by disease or injury at birth and choreo-athetosis, spasticity, ataxia or some other type of hyperkinesia is present, the tendency in prescribing treatment is to place too much emphasis on physical training without due consideration of the effect that repetition of an activity has upon the growth of the behavior pattern at various stages of development. Stepping movements, for example, show themselves almost immediately at birth but no amount of exercise is going to enable the normal infant to walk until his nervous system has attained adequate differentiation. In the case of the cerebral palsies there are also limits circumscribed by anatomical and physiological growth beyond which no amount of exercise will help the patient and in fact the overdoing of such exercise may even lead to greater difficulties, as for instance, in the case of the mother who ties up the good hand of the hemiplegic child thinking that the more he uses the maimed member the sooner it will be normal. She often creates speech disorders and behavior difficulties which are far more serious than the original handicap. Now and then one comes across a spastic whose physical training has been almost negligible, who becomes an author, a teacher, an attorney, a librarian or a successful business man in the face of what seem to be insurmountable difficulties, while another spastic whose physical affliction is slight in comparison and who possesses average intelligence becomes anti-social in spite of having had supposedly the best of muscle training, all of which makes one feel that the more important part of treatment has been neglected, namely that of developing the assets which the child already has at his disposal and aiding him in adjusting to his handicap and the conditions of life as he finds them. As the child develops the unimpaired areas of his brain and acquires outside interests, there is a corresponding improvement in muscle control, as is exemplified in the case of the spastic girl who is so muscle conscious during meals that she cannot feed herself but nevertheless is able to forget herself in music to the extent that she plays the piano most satisfactorily. The fact that a spastic athetoid is able to maintain perfect control of his muscles when fear, anxiety and self-consciousness are in abeyance should be evidence enough that progress in the treatment of such conditions does not rest in exercises which will make the patient all the more muscle or speech conscious but rather in applying measures that will tend to reduce to a minimum the number of sensory stimuli to which the patient is unaccustomed to attending simul-

* Delivered in part before the General Sessions, American College of Physicians, Detroit, March 2, 1936

taneously In this paper I shall relate observations on the effect of sensory stimuli on muscular activity in cases of cerebral palsy

During sleep, when sensorial impressions are reduced to a minimum, the purposeless movements cease and the muscles invariably attain relaxation even in the worst cases of spasticity and athetosis Contrary to one's expectations, after a good night's sleep, the patient is usually worse during the morning hours A mother will relate that her child is unable to feed himself at breakfast but finds little or no difficulty with the evening meal The thought processes are also reflex activities and in the case of the spastic athetoid may be as hyperactive as the knee jerk His power of concentration is therefore limited, and is reflected in overflow motor activity, which grows less as the child gets into the routine of the day's play or work and the sensory stimuli, which his nervous system is unaccustomed to handling simultaneously, are lessened The value of an academic program in helping the spastic athetoid of good intelligence cannot therefore be overemphasized Parents who delay academic training until the child acquires better control of his hands or speech are surprised at the rapid improvement in muscle control which follows when the child is finally allowed to go to school

When the spastic athetoid emerges from a deep sleep to the waking state and is suddenly confronted with more sensory stimuli than his defective nervous system can adequately handle, we find a corresponding sudden change from a state of complete muscular relaxation to a state in which the patient exhibits his least ability to control muscular movements If the change from sleep to the waking state is more gradual, as for example during the recovery from the effects of ether anesthesia, the patient's ability to control his muscular movements will be at its best when he emerges from the ether and will become progressively worse as the effects of the ether wear off In taking histories of cases of choreo-athetosis with and without spasticity, it is a common experience to find that patients or their relatives volunteer that much of the choreo-athetosis and spasticity have been lost for a short time after recovery from ether anesthesia after surgical operations One mother related that the first time she had ever been able to understand the speech of her spastic athetoid and dysarthric child was when the child was recovering from the effects of ether following a tonsillectomy I have had occasion to witness a child under similar circumstances There was little or no dysarthria when the child was coming out of the effects of the ether As the ether wore off the child's words became less and less distinct and finally the speech became as dysarthric as before the operation

In an illustrated lecture before the American College of Physicians in 1936, I showed movies of the effects that alcohol had on controlling athetosis and spasticity in the case of a man of 45 years of age He was unable to bring a full glass of water to his lips without spilling half the contents After drinking two ounces of whisky he was able to handle a full glass of

water without difficulty. At no time during the alcohol experiment was any evidence present of impairment of intellectual processes, of dullness, stimulation, euphoria, or loquaciousness. The patient was not an addict to alcohol although he had been aware of its effects for many years. The subjective feelings of one such patient were interesting, his comment being "Alcohol does not necessarily make me do things better, but makes me forget the things which I do badly." Another comment was "My friends tell me that I am more drunk when I am sober than when I have had a drink."

The majority of observers have explained the origin of choreic and athetoid states on the basis of basal ganglia damage. There is reason, however, to speculate as to their possible cortical origin. Suffice it to say that the effects of alcohol are supposedly those of reducing the activity of the higher centers of the nervous system. Under the influence of alcohol, the lower centers (basal ganglia) retain a certain degree of autonomy and can carry on their functions without being influenced by the damaged cortex. It is difficult to explain the observations made unless one accepts the theory that alcohol diminishes the domination of the higher cortical structures over the dependent and phylogenetically older lower centers. Possibly the mechanism is an elevation of the sensory threshold by alcohol and a corresponding reduction of the number of sensory impulses reaching the higher centers.

If choreo-athetosis and spasticity can be abolished through administration of ether or alcohol, then other measures of cutting down sensory stimuli should be equally effective in controlling adventitious muscular movements. It must be emphasized, however, that these stimuli are not to be eliminated altogether but should be reduced to the minimum necessary for the production of a well coordinated motor act. In the case cited above of the athetoid child who spoke better when under the influence of ether, too much of the drug caused cessation of all activity and too little was without effect—but when the concentration of ether was such that sensory stimuli were depressed just enough, then the act of speaking was almost perfect.

McGraw made observations on the behavior of the normal infant who was just beginning to extend his arms to reach for an object in the visual field. She showed that if the sight of the object is excessively stimulating the energy which should be directed toward extension of the arm in the direction of the object becomes converted into disorganized general body activity. Too little interest in the object would fail to stimulate movement in the direction of the object and too much interest would interfere with the individual's control over the motor activity involved. It is desirable that the individual should be interested in the object just enough to elicit a well controlled motor act. McGraw found that if the child was allowed to handle the object before reaching for it and thereby increase his sensory

experience the excess motion in the reaching prehensile act would be eliminated

I made a related observation in the case of a spastic athetoid patient who was given blocks to pile up on a table. He placed the first one on the table with only slight athetosis. The placing of the second block on the first was done with an increased amount of overflow activity, which was further augmented when the third was placed on the second. The fourth could not be placed at all and the whole pile was knocked down. This was repeated several times with more or less the same results. The patient was then made to wear a pair of partially opaque glasses which cut down his vision to the blocks and the immediate vicinity of the table. He was then, after a few trials able to place one block on the other without as much overflow and was able to pile more blocks than before. One must not draw the conclusion from this that merely fitting a pair of dark glasses to such a patient is going to relieve him of all his athetosis, but it does show that in this particular case excess visual stimuli did play a considerable part in the production of overflow activity. I was impressed by the effect that cutting down visual stimuli had in enabling an athetoid young man to feed himself in the presence of others who were watching his grotesque muscular movements during a meal in a restaurant. The more apprehensive he became of the people watching him, the greater was his difficulty. Being very myopic, he removed his glasses and not being able to see the others as well as he did before, he finished the meal without any trouble.

In helping a spastic athetoid to use his hands, it is often surprising to find how a slight pull over a muscle or tendon (proprioceptive sense) will prevent an overflow of muscular activity and will enable the patient to maintain perfect control as long as we keep the pressure there. By means of using a small iron disc fastened with adhesive tape to the skin I have through the force from the electro magnet on that disc been able to study the effects of a pulling force on a particular muscle group. In a subsequent paper, I shall report these findings.

The spastic athetoid has difficulty in correlating muscular activity and perception. He tries to look in too many directions at once. In shaking hands he thrusts his hand out aimlessly. If before shaking hands he is asked to look sharply at the thumb of the hand he is trying to reach, he will have no difficulty in shaking hands. Speech is likewise improved when the spastic athetoid focuses his eyes at a certain point in speaking. This is one of the reasons why lip reading is valuable in helping the general type of dysarthria present in spastic athetoid cases. If the person has to read lips he will obviously have to look at the one whose lips he is reading and in so doing he cuts down his vision with a consequent decrease in adventitious muscular activity. In learning to walk, the patient looks in every direction except where he is walking. This was illustrated in an athetoid case with considerable ataxia. In attempts to walk, the patient would stagger along

like a drunkard not looking in the direction of his walking and holding his arms flexed at the elbow and wrist. When he was told to focus his eyes steadily at a point in the direction of his walking, the overflow movements ceased, his gait became better and the arms came down to his sides without the patient being told to bring his arms there. When this same patient had to walk in total darkness, he became terrified and could not take a single step without falling. One dark evening when this patient was walking outside in a pair of white shoes, I noticed that his gait was better than I had ever seen it on previous occasions. The darkness of the night in cutting down his vision to the white shoes and the road, eliminated excessive motor activity. Here we have a child who is hardly able to walk in full daylight, is not able to walk at all in total darkness and yet, is capable of obtaining an almost normal gait when the visual stimuli are cut down to the proper amount.

According to McGraw the origin of many childhood "fears" may be attributed not necessarily to some unpleasant experience and its resultant associations but to a natural growth imbalance or lack of integration between several aspects of development. A child walking in the dark will show muscular tensions if his perceptive development is at such a stage that it does not integrate smoothly with the motor adjustments involved. This attitude may persist until it constitutes a "fear" of the dark. If the child's experiences are treated casually, the tension resulting from normal growth imbalance will soon fade except to the extent that a degree of tension may be needed for handling the situation. If a natural growth imbalance contributes to the development of an attitude of fear in the normal child, how much more should not such a factor be responsible for producing a similar attitude in cases of cerebral palsy where disease or injury is primarily responsible for growth imbalance.

Studies by Brickner and Lyons on individual acquired automatic associated movements in cases of encephalitis show that the organism remembers the acquired acts while instinctive acts are impaired. They cite as an example the case of a man who was a star pitcher for the New York Giants until six years before when he contracted definite and typical epidemic encephalitis. He is able to walk only with difficulty and all his routine motions are made with the usual retardation. In their test the man stood on the lawn of the hospital, his head and shoulders stooped, his hands trembling, his whole attitude one of characteristic rigidity and immobility. But when a ball was thrown to him, his whole body immediately became plastic, he made a perfect catch out at the side and at once threw the ball back. The whole act was characterized by a beauty and grace not attainable by the ordinary normal man. Brickner and Lyons state that "specific acquired acts in which grace and automaticity were achieved by the individual patient, prior to the onset of the illness can still be executed by patients with epidemic encephalitis despite rigidity."

In the introductory paragraph of this paper, the case of a spastic girl was mentioned, who is so muscle conscious at meal times that she is unable to feed herself, but is nevertheless able to forget herself in music to the extent that she plays the piano quite satisfactorily. Mention should also be made of a bacteriologist who has great difficulty in feeding himself but is nevertheless most successful at his profession. Still another case is that of a spastic athetoid whose difficulty is in feeding himself and yet he is able to play golf and compete with many normal men, in fact, his ability is so great that he might some day become a professional. The ability of the encephalitic to catch a ball in spite of rigidity and the ability of the congenital spastic athetoid to play the piano in spite of not being able to feed herself, suggest that the factor for the preservation of skilled acts in the case of the encephalitic must have something in common with the factor for acquiring a skilled act in the case of the spastic athetoid. This common factor is of interest.

The beginner at the piano may experience as much difficulty in placing the right finger on the right key as the spastic athetoid does in learning to handle a cup. Through practice the piano player learns to limit movement to certain muscles and eventually is able to play a well practised piece without much conscious effort. The difference between a normal person acquiring a skilled act, such as playing the piano, and the spastic athetoid learning to handle a cup is not so much a matter of complexity of muscular movement, as it is direction of attention upon the purpose of the act. The pianist is not interested in muscle training per se, but in a purpose, he wants to play and his muscular skill increases as he forgets himself in his music and learns to play without conscious effort. The hand of the spastic athetoid likewise becomes more agile as he forgets himself in his work. This is illustrated in the case of a chemistry student with a bilateral athetosis. He could hardly feed himself when he entered college. Through studying chemistry he developed considerable manual dexterity. When he started laboratory work, fear of acid burns made him spill solutions although he had no difficulty in handling two empty beakers. As he learned to pay more attention to the chemistry problem involved in his laboratory work, fear abated and manual control increased. The manual ability thus gained meant more to him than any amount of conscious muscle training he had ever undertaken.

The value of routine exercise cannot be determined by how well the spastic athetoid performs in the treatment room. I know spastics who perform splendidly in an environment to which they are accustomed but who go all to pieces when confronted with new situations. The spastic therefore needs something more than physical training to fortify him when he faces the new conditions of life and is confronted with more sensory stimuli than he can adequately take care of.

Merely to teach him to let go of his tense muscles by thinking of a rag

doll on such occasions is not going to solve his problem. Neither will ether, alcohol, luminal or other sedatives, in spite of their effects on cutting out sensory stimuli, yield any permanent results. The patient must develop the assets which are already at his disposal. As these assets are given opportunity to develop, the patient begins to feel that he is an integral part of society instead of an ostracized member. His greater assurance and confidence will make him more oblivious of his condition and less apprehensive of his shortcomings, all of which tend to minimize the sensorial input with a consequent increase in equanimity.

We are becoming more aware of the importance of vocational guidance and of the direction of the education of normal children towards equipping them to enjoy a full life. The value of providing the child with the means of manifesting its ability in one way or another has long been recognized. Why should we not have schools which, in addition to providing physical training, will be equipped also to enable the spastic to gratify in acceptable ways his desire for personal worth? The spastic athetoid who sits all day waiting for his next exercise and watching the activities of normal children cannot help but develop an attitude of anxiety or resort to daydreaming instead of the contemplation of reality. Such a child is helped by placing him with a group of handicapped children of average mentality assuming that his rating is such that he can learn to compete and develop a sense of importance.

The delay in the mental development in the spastic athetoid group is usually attributed to the lack of that type of mental growth which is stimulated by grasp and touch in every normal child. I feel that the reverse is truer, that is, the defect in muscular control is accounted for by the lack of a rounded education program for that child. The aim of such a program should be to develop objective interests which lead to the cutting down of sensory stimuli to those connected with the act that the patient is performing. The spastic athetoid cases mentioned above who have difficulty in feeding themselves and yet are able to do skilled acts satisfactorily like playing golf, playing the piano, and working out problems in chemistry and bacteriology behave in such fashion because such activities hold their interest whereas feeding is such a routine procedure that they are unable to develop interest in the act sufficiently to forget the things they do badly.

Between 15 and 20 per cent of crippled children are victims of intracranial hemorrhage. In some states the percentage is as high as thirty. It is maintained that nearly all of such cases develop serious behavior difficulties later in life. In the spastic athetoid group an estimate of the intelligence is often obscured by the muscular defects to the extent that they may be falsely regarded as completely defective in mentality or as possessing normal mental potentialities capable of development under physical training. It is pathetic enough to see a mother bring a mentally defective cripple to the clinic for physical training year in and year out in the hopes that as he gets

the use of his hands his intelligence will increase proportionately and will eventually approximate normal. But nothing is more heartbreaking than an intelligent child with a spastic arm or leg approaching adolescence who in spite of having had the best muscle training is rapidly becoming markedly introspective because of his inability to adjust to his handicap. In some instances the milder the physical affliction the more severe is the mental handicap. When faced with new situations, the spastic generally takes the easiest way out. In school the teachers are lenient with him and should he not know the answer required it does not take much effort to appear more nervous than usual and thus invariably the teacher refuses to press him, taking it for granted that he knows the answer.

I know one successful business man who completed high school in that way. He attributes his success not to his feigning in high school but to a strict master in college who would not let him hide his ignorance behind an exaggerated athetosis. The result was that he had to repeat his first year in college. He was given every opportunity to prove his worth. Extended time was allowed him in taking examinations but he had to learn to face reality. He had to recognize the fact that the things he had formerly been praised for—such as ability to bring a cup to his lips without spilling, an act expected of everybody without comment—did not constitute the things of major importance in life. The spastic is often made to feel that his main purpose in life is to live to get well, rather than to learn something that will compensate for his afflictions. Is it any wonder then that we read such sweeping statements to the effect that two-thirds of the cerebral palsies are mentally defective? And this refers not only to the severely handicapped, but as well to those so slightly motor handicapped that they cannot be called crippled.

In discussion of the latter group, it is often mentioned that they are unable to progress from the infantile stage. Intellectually function may be little impaired, while effectively these individuals show disturbance or even incapacity of judgment and practically behave as weak-minded. Their social adjustment is interfered with because of their proneness to an attitude of foolish cheerfulness, of nonsensical levity, or of lack of reserve, which their vain self-satisfaction accentuates. Such cases are probably much more frequent than would be noted merely from those who fall under clinical observation, since the physical affliction is so slight.

To dismiss this group and say that nothing can be done for them because their anti-social behavior can be explained by a slight intracranial hemorrhage is as absurd as thinking that the one armed man cannot adjust to his handicap and become a useful citizen. I have seen many such children become socially adjusted through placing them for a time with a physically handicapped group with whom they can learn to compete. Having once gained self-assurance and confidence that their inferiority can be adequately compensated for, they feel their worth is proved. This belief can then be carried over into other situations.

One striking example is the case of a boy of 12 years whose muscular handicap was so slight that it was noticeable only when he became embarrassed or had to face new situations. In school he did not get along well and was several grades behind his age. He complained of headaches and had to be excused from class several times a week. By placing this boy with a group of handicapped children of average intelligence where he was able to show them how to play ball and swim, it did not take long until he was up to the average class. What he gained at camp he was able to carry over most satisfactorily in a normal environment.

The problem of the cerebral palsy child, and this can also apply to the nervous child in general, is not going to be solved by establishing large hospital schools where hundreds of such cases can be taken care of. Such a child needs guidance in helping him meet new situations, and not institutionalization. There are adequate facilities in most of our larger cities for diagnosing and prescribing treatment for the birth injured but the prescription is one that cannot be filled in the corner drug store. The establishment of special schools running in conjunction with the local board of education where the mental and physical development can be simultaneously controlled will enable the child to receive the prescribed treatment. There should be a centralized hospital school for diagnostic and teaching purposes where parents and teachers can be instructed in handling these cases. Cases accepted for education and treatment in these schools should be selected according to the severity of the lesion, the age of the patient, the degree of the intellectual impairment, whether a progressive disorder or whether a hereditary affliction. This calls for not only careful clinical examination to detect the special disabilities but also careful analysis as to the intelligence rating. At times encephalogram studies and careful psychiatric and sociologic investigation are necessary.

Since the infantile cerebral palsies do not constitute a single disease with a single etiology, a detailed history is necessary to rule out the progressive types of disturbance which are not amenable to therapy. The severity of the lesion or the diagnosis of the condition in doubtful cases can be estimated frequently by the use of the encephalogram. This proved to be the case when identical twins with a history of instrumental delivery accompanied by cyanosis, a disturbance of gait, speech and general incoordination were presented for observation. Had only one twin survived, the conclusion would have been that the condition resulted from birth trauma but the evidence of identical twins with identical brain defects, which encephalograms revealed, made any other cause than failure of development impossible. Obstetrics is often unjustly blamed for producing many of these conditions. While we should manifest a greater concern to the ends of encouraging better prophylactic measures and after treatment, at the same time it is important to bear in mind that unless the factors contributing to the cause of the disturbance are more accurately ascertained, and no one is un-

justly blamed for producing the condition, we are not going to get the co-operation of physicians in stimulating interest in the establishment of schools where cases of infantile cerebral palsy can be properly trained. Neither must it be concluded that just because we make a diagnosis of birth injury we are dealing with a fixed type of brain injury. Dyke, Davidoff, and Masson have shown that a porencephaly due to trauma may cause a progressive type of disorder. A traumatized nervous system, on the other hand, is more susceptible to infections and not infrequently there may be a superimposed encephalitis. At adolescence the difficulties are sometimes accentuated because the patient then becomes more conscious of his affliction. Aside from the progressiveness or non-progressiveness of the disturbance a clinical examination should reveal what contributes to the status which the muscles are in. Is the atrophy one of disuse or has the lesion interfered with the nutritional centers of the brain? It is not only necessary to know whether the muscles are spastic, athetoid, ataxic, etc., but more important is to know the type of sensory stimuli which tends to keep them in that condition. We have mentioned the importance that visual stimuli play in learning to walk, to control the hands and in talking. It is often surprising to find that a patient who has never been able to walk will do so shortly after the surgical correction of a strabismus. I have also seen head shaking and other adventitious movements disappear after muscles necessary in controlling the eyes have been treated. Almost 15 per cent of the cerebral palsy cases which have come to my attention have definite impairment of hearing, sufficiently to interfere with their speech development and education. They are not deafmute, or aphasic. Just as color-blind persons are blind to one end of the spectrum, so others may be deaf to one end of the tonal scale. There are special methods for diagnosing and treating such conditions. Obviously if a person with cerebral palsy has a reading disability or educational difficulty he is not going to profit from the ordinary classroom routine, and special training in addition to his muscle therapy has to be devised. Care must therefore be exercised in differentiating between a special disability and a deficiency. The latter is not amenable to treatment, whereas a special disability, such as in speech and in reading and writing, can often be overcome under proper training.

The treatment of infantile cerebral palsy in contrast to that of anterior poliomyelitis requires that more attention and thought be given to the sensory side of the reflex arc. In this paper an attempt has been made to show the influence that selective inhibition of sensory stimuli has on the patient's ability to control his muscles. During sleep the adventitious muscular movements cease. The effects of ether, alcohol and sedatives were mentioned. The effects of reducing or concentrating visual stimuli in talking, walking and use of hands were noted. The effect of selective inhibition of sensory stimuli by developing interests in piano, golf, chemistry and bacteriology was pointed out.

In conclusion it may be said that those natural or environmental stimuli which affect the normal individual also affect the cerebral palsy. Indeed it is indisputable that the cerebral cortex receives these stimuli, visual, auditory, proprioceptive sense, etc., summates these stimuli and transfers them to their proper channels for their final release through motor or other pathways. In the cerebral palsies where there is considerable damage to the cerebral cortex and the ideational centers are preserved these stimuli affect the injured brain in a manner shown in the individual cases. A shunting of one or more sensory stimuli will affect the cortex in degrees and thus the final release will be somewhat more towards the normal, as for example, the spastic athetoid cases mentioned who have great difficulty in doing simple acts like feeding themselves and yet are able to do skilled acts satisfactorily like playing golf, playing the piano, and working out laboratory problems in chemistry and bacteriology. With educational training new channels of release will be provided, a partial inhibition of sensory stimuli will be accomplished, and in due time a summation of these sensory stimuli will result in more or less the normal manner.

THOUGHTS ON HYPERTENSION *

By DAVID RIESMAN, M D , Sc D , LL D , F A C P ,
Philadelphia, Pennsylvania

WHETHER hypertension is a disease or a symptom is a much debated question. It can, I believe, be answered rather easily, for the present at least, in the following way. When we know the cause or the apparent cause we emphasize it and consider the hypertension as part of the symptom complex. When we do not know the cause we look upon the hypertension as the disease itself. On this basis such hypertension as that of chronic nephritis or aortic insufficiency is a symptom, while that of unknown cause is a disease entity. Such a disease entity is represented by essential hypertension.

Although my main object is to deal with essential hypertension, I shall for purposes of clarity give a tentative classification of hypertension. As long as our knowledge of the etiology is limited, such a classification has to be mainly clinical.

CLASSIFICATION OF HYPERTENSION

- 1 Primary, essential or arteriolosclerotic
- 2 Arteriolitic or malignant
- 3 Nephritic
- 4 Secondary or accidental
 - (a) Aortic insufficiency
 - (b) Coarctation of the aorta
 - (c) Adrenal tumors
 - (d) Pituitary basophilism
 - (e) Hyperthyroidism
 - (f) Pregnancy
 - (g) Enlarged prostate
 - (h) Arteriovenous aneurysm

Subclasses

- 1 Juvenile
- 2 Superhypertension

I need say little about this classification—it is largely self-explanatory. With regard to malignant hypertension, I might say that I do not believe it is a late stage of essential hypertension. It is a different disease and has all the earmarks of a distinct clinical entity. In my experience it has occurred earlier in life than essential hypertension. The diastolic pressure is much higher than in the majority of cases of the latter. Renal changes are pronounced. The peripheral vessels are thickened, tortuous, tense and hard.

* Read by invitation before the Academy of Medicine of Northern New Jersey, Newark, New Jersey, May 11, 1937.

Retinal changes are present. The patient looks pale and sallow, his color has been compared to that of a cold buckwheat cake. Cerebral accidents are common.

On account of the necrotic inflammatory changes in the arterioles, the term arteriolitic hypertension is applicable.

The secondary types of hypertension need not detain us, except to say that the hypertension in some of the conditions is compensatory, in others, the connection between cause and effect is obscure.

Juvenile hypertension and superhypertension are entirely arbitrary classifications. By juvenile hypertension I mean a premature hypertension occurring usually from just before puberty to about 35 years. My associate, Dr Stanley E. Harris, has found many instances among students at the University of Pennsylvania and I have seen a number of examples in my office. We admit to this class only those cases in which the blood pressure has been repeatedly tested and found elevated—150 and upwards.

Superhypertension is applied to those cases in which the blood pressure is 260 and higher. I have put them as a separate class so that I can better watch them and note their progress. Such a procedure will eventually be helpful in arriving at a more securely based prognosis. I have had under observation a considerable number of women with systolic pressures of 270 who lived for many years. One, a member of my own family, who for over 30 years had a pressure of from 200 to 275, was nearly 100 years old at death.

Essential or primary hypertension is the most important type, being responsible for 15 per cent of all deaths after the age of 50 years*. It is the principal factor in what I have called *the failing heart of middle life*. The most striking objective result of essential hypertension is enlargement of the heart. At times one finds the heart enlarged in the absence of valvular disease and of concomitant hypertension. In the majority of such cases we may infer that a hypertension existed previously but had disappeared.

I shall not discuss in any detail the theories advanced in explanation of essential hypertension, because I should have to say after each one "not proved." A few points of interest may however be mentioned.

Hypertension is uncommon among the Chinese. Even foreigners living in China tend to have lower blood pressures (Foster¹). Gunewardene² examined 200 Buddhist priests ranging in age from 30 to 80 years and found only one instance of real arterial hypertension. This striking difference between the oriental and the occidental has been attributed to differences in stature, muscular development, climate, habits of diet. But none of these nor all of them combined are sufficient to explain the difference. The greatest difference lies in their respective attitudes toward life. To the Buddhist priest the restlessness, the consuming ambition of the western business man are unknown and incomprehensible. He is never in a hurry,

* Cardiovascular disease, and in this hypertension is the chief factor, causes four times as many deaths as cancer.

never runs, not even as Gunewardene says, if his robes caught on fire His only concern is life after death or some metaphysical problem The placidity of the Chinaman is proverbial

Foster thinks that in the Chinese the widespread use of watermelon seeds which apparently contain a substance that depresses blood pressure may be another factor in the lower vascular tension of the Chinese

Of etiologic factors often not sufficiently appreciated I want to refer to two

1 The possible influence of psychologic disturbances both in causing permanent hypertension and in producing temporary rises above the patient's habitual level Disturbances in the sexual sphere, frustrations, etc., mental strain from business or domestic worries, unsatisfied ambition—seem to be capable of raising the vascular tonus

2 Heredity That heredity is an influential factor in hypertension is easily demonstrated, but that is merely a statistical fact which offers no fundamental explanation We do not know what genes transmit the tendency or where the point of attack is on the blood vessels—on the vasomotor mechanism or on the musculature of the vessels, or back of both, on one or more of the hormone-secreting glands The problems are endless

It seems logical to place the immediate cause of hypertension in the arterioles, in the precapillaries What is the nature of the process in the vessels? The variability, the lability of the blood pressure in essential hypertension, the absence of structural, that is inflammatory or degenerative, changes in the arterioles in hypertensive persons dying in the early stages of their hypertension, suggest that spastic constriction of the arterioles in a large vascular bed such as the splanchnic area is the likely cause For that reason I would make arteriolospastic and essential synonymous words

Having carried essential hypertension back to the arterioles, to arteriolospasm, still leaves unanswered the question, what is the cause of the spasm It is most probably chemical or hormonal in nature It would, however, be an incomplete view of essential hypertension if we considered merely the angiospastic phase The human system is an integration of innumerable quasi-independent mechanisms in harmonious relation, in homeostasis, to use Cannon's word, achieved by the self-steering of all the organs and tissues of body If the neurovascular system shows evidence of disturbance as in hypertension, many fine adjustments are necessary to keep the body functioning At any point in these interdigitating mechanisms a breakdown may occur We are often unable to recognize the early signs of such a breakdown, one reason being that our thinking has hitherto been too anatomic and not enough physiologic It is necessary to study many things At one time the nervous control of the heart was considered the main element in cardiac contraction, until the myogenic theory gained preeminence Perhaps we are at present giving too much prominence to the vasomotor mechanism and not enough to the intrinsic myogenic capacity for contraction and dilatation of the blood vessels

Symptomatology Essential hypertension may be symptomless for many years. It is often accidentally discovered during insurance or health examinations. As long as the heart is competent and able to counteract the resistance in front symptoms are minimal or absent.

The inaugural symptoms are mainly subjective—dizziness, headache, ringing in the ears, palpitation, slight dyspnea on effort, a sense of weight in the chest, nose bleed and irritability. Naturally these need not all be present. There may be only a single one in the beginning. The patient may ignore these symptoms or the unobservant doctor may overlook their cause, contenting himself with purely symptomatic treatment. Such patients eventually come under observation for more pronounced symptoms. These are most variable but are principally cardiac, cerebral or gastric.

The cardiac manifestations are those of early congestive failure—subjectively, dyspnea, objectively, peripheral edema, basal pulmonary congestion or unilateral hydrothorax. These, especially the latter two, must be looked for, otherwise they will be overlooked.

A rarer symptom, which might be called cardiopulmonary, is acute pulmonary edema, which has a tendency to recur at intervals and usually comes on at night. Air hunger, a sense of suffocation and fear of impending death, together with intense cyanosis, the physical signs of pulmonary edema, and at times but not constantly the expectoration of blood-tinged frothy fluid are the characteristic symptoms.

An attack of angina pectoris or of coronary occlusion may be either an early or a late symptom.

If the patient presenting such symptoms is carefully examined one or more of the following conditions will be found:

- 1 A high systolic and a relatively low diastolic pressure
- 2 Cardiac enlargement
- 3 Accentuated second aortic sound
- 4 Often a systolic murmur at the aortic area
- 5 In late stages a systolic murmur at the apex
- 6 The radial vessels are usually soft but the temporal arteries are often tortuous
- 7 Arcus senilis or annulus senilis
- 8 There may be basal râles
- 9 Hydrothorax, generally unilateral
- 10 Edema of the shins and ankles
- 11 Changes in the retinal vessels

The electrocardiograph may show left axis deviation, in cases of long standing hypertension the degree of axis deviation may be marked, with prolongation of the QRS interval beyond the accepted top normal figure (0.1 second) due to increased conduction time through an hypertrophied ventricle. T_3 may be inverted and, according to Master, T_1 may also be inverted.

Many clinicians in speaking of the enlarged heart of hypertension use the term myocarditis. Strictly speaking this is not correct, for only rarely is there any evidence of inflammatory changes. Nevertheless, the heart muscle gives out. In order to get rid of the inappropriate term myocarditis, I have proposed myocardosis as a generic term to imply a functional rather than a structural change.

Cerebral Symptoms These are extremely interesting and important for the understanding of the morbid physiology of hypertension. As a rule the disturbances are transient—hemiplegia, aphasia, monoplegia—and are usually ascribed to local angiospastic states. In severe cases generalized convulsions may occur which are often wrongly called uremic or epileptic. There may be no evidence of kidney damage and, setting in late in life, after fifty, they are not true epilepsy. Some speak of the condition as hypertensive encephalopathy, it is also called epilepsia tarda.³

During the convulsive seizure, and also in other types of encephalopathy before the onset of the particular symptom there is usually a sudden and abrupt rise in the systolic blood pressure, at times to 280 or even 300.

The focal symptoms mentioned above may last from a few minutes to 24 or 36 hours and may then subside without any residue. However, I have observed in numerous instances the persistence of one particular symptom, namely conjunctival anesthesia on the side that had been affected. I found this even in cases in which there was no anesthesia of the general body surface.

Besides angiospastic complications hypertension may lead to thrombosis and to rupture of cerebral vessels, i.e., to apoplexy, which is a frequent but by no means the most frequent mode of death in essential hypertension.

The gastric symptoms of hypertension are the gastric symptoms of the myocardial weakness, of the myocardosis, associated with and usually secondary to the hypertension. In the majority of instances the chief complaint is fullness and gaseous distention. Such a complaint by a person past 50 years who previously was free of digestive disturbances, is never to be treated lightly—it may mean the beginning of malignant disease or the failing heart of longstanding high blood pressure.

Diagnosis It is important to make the diagnosis of essential hypertension in the early stages for the treatment will then be of most avail. A systolic blood pressure of 140 to 150 in an individual under 40 years is not to be ignored. Naturally it must be checked by several readings on different days so as to eliminate the factor of fear or excitement. A labile blood pressure showing wide swings from high to low is common in persons who later show a permanently elevated blood pressure.

The family history may be of significance. A history of hypertension, apoplexy, chronic heart or renal disease constitutes a background for hypertension in the descendants.

What shall be our criteria for the diagnosis of essential hypertension? As I view the subject these criteria are

- 1 A persistently high systolic pressure
- 2 A relatively low diastolic pressure
- 3 Absence of disturbance of renal function
- 4 Normal blood chemistry, that is as regards urea nitrogen and chlorides
- 5 Absent or minimal eye changes
- 6 A symptomatology trivial compared with the height of the systolic pressure

At this point I might say something about prognosis, since due attention to that rather neglected phase of medical practice may help us in dealing with our patients. I shall be somewhat dogmatic as unconditional statements are more useful, provided they are favorable, in quieting the patient's mind.

- 1 An individual can live to be 80 or even 100 years with high systolic blood pressure
- 2 Women bear high blood pressure better than men
- 3 The diastolic blood pressure is more important as a prognostic index than the systolic blood pressure. A low diastolic blood pressure favors relative longevity
- 4 Good renal function—traces only of albumin or no albumin, a few hyaline casts, good concentration—is a favorable prognostic finding
- 5 Moderate cardiac hypertrophy is not unfavorable
- 6 Cerebral accidents even of apparently trivial nature as well as anginal pain and retinal hemorrhages are all ominous signs

Treatment The treatment of essential hypertension is psychologic. By that I mean that it must be addressed to the intelligence rather than to the stomach of the patient. Such treatment ought to be part of our general scheme of preventive medicine in the sense that we should know the vascular characteristics, the tubing as Osler called it, of our patients and of their children. It certainly would give us valuable information if we were to examine the children of a man or woman in whom we had discovered high blood pressure—we might be able so to shape the lives of these persons as to guard them against hypertension in later life. To do all this means addressing ourselves to the minds of our patients and making them understand our aims.

We must assure our patients with essential hypertension of the comparative harmlessness of high blood pressure. To some extent we physicians have been responsible for making the laity blood-pressure-minded. A goodly number of patients have come to me all in a tremble saying, "Doctor, I've got blood pressure." When we can conscientiously do so we must relieve such persons of their anxiety.

Is it wise to tell the patient who has hypertension what his blood pressure is? Here the psychologic insight of the doctor and the general circumstances of the case must be the guide. My rule is this. If the patient is cooperative, then there is no need of his knowing his top figures. If he

is uncooperative, then it may do good to tell him so as to scare him into good behavior

Many hypertensive patients overwork, overeat, undersleep, and over-smoke. All these departures from the norm must be corrected. The man who takes to bed with him "the cares that infest the day" must be educated in a better habit. Attention must be given to the sexual life in both sexes—not that we can often help, but we can better understand. In some cases we can actually help—by advising infrequency of coitus when dealing with patients with superhypertension or with those approaching it.

Diet Dietetics is the weakest subject in medicine. One can find authority for almost any conceivable diet for any human ailment. At one time it was customary in hypertension to give a salt-free, low-protein diet. However, excepting in those who indulge in meat and salt to excess, such extreme restriction was of no particular value in reducing blood pressure. All it did was to make the patient's life miserable. Moreover, Vilhjalmur Stefansson has shown that one might subsist on an exclusive meat diet for a year without any elevation of the blood pressure. Yet that might not apply to one who by heredity was destined to have high blood pressure, for such a one a low protein diet may be wise.

I think physicians are generally agreed that quantity is more important than quality, especially if the patient is overweight as is so commonly the case. We serve our patients best by teaching them moderation.

Alcohol has been under suspicion but in my opinion unjustly. It is true many free drinkers are hypertensive but such men as a rule are also free livers. A little whisky or a social glass of wine does no harm to the blood pressure.

With respect to tobacco, my opinion is quite different. I usually advise a minimal amount of smoking and if the patient has had cardiac pain I as a rule forbid tobacco altogether.

The bowels need attention. The patient should have a regular, easy, daily movement or two movements without straining. If need be, he should take a laxative, such as mineral oil or compound licorice powder. Toxic symptoms—occipital headache and mental depression—are sometimes quickly relieved by a colonic irrigation but this is not needed with any great frequency.

I have found in particularly constipated people that a weekly dose of castor oil is helpful.

Exposure to the hot sun should be avoided.

Exercise within reasonable limits is permissible. The trouble is to find the "reasonable limit." Wading in a swift stream to catch trout or salmon involves not only a severe physical but also an intense emotional strain—more than is good for a hypertensive fisherman. A prolonged golf game in the hot sun is likewise fraught with risk. Then there are persons, usually bankers or captains of industry, who are given to violent home gymnastics.

—their habits must be studied and modified to suit their cardiovascular condition

Medicinal Treatment There is no specific drug in our pharmacopeia that will permanently lower arterial blood pressure. Many have been recommended, all have been found wanting. Their very number is proof of what I have said. I have used bismuth subnitrate, potassium sulphocyanate, and various organic extracts. They have all proved unreliable. Does that mean we are powerless in dealing with hypertension? By no means. The best results are obtained with sedatives, particularly those of the barbituric acid group. Phenobarbital in one form or another is very useful. The bromides are also helpful. One can combine them with advantage with elixir phenobarbital. I also like chloral hydrate which in reasonable doses is perfectly safe.

When the pressure is high and the heart begins to labor or convulsions occur or acute pulmonary edema, venesection often brings about immediate and dramatic relief.

In women at the menopause it is perhaps rational to try some of the endocrine products. If one takes the words of detail men or of the pharmaceutical literature as gospel, then these are sovereign remedies. We need to know a great deal more about them before any such statements can be made.

When the pressure is abnormally high, one may give the nitrites. I prefer for regular use erythrol tetranitrate in doses of 0.015–0.03 ($\frac{1}{4}$ to $\frac{1}{2}$ grain). In any emergency and when the patient has cardiac pain nitroglycerin under the tongue is the best remedy.

Roentgen-ray therapy has been used on the adrenals and on the pituitary gland, the latter on the theory that pituitary basophilism might be the cause of essential hypertension. The data are as yet insufficient for a definitive conclusion.

Physiotherapy, including diathermy, has been tried—personally, I have not seen much benefit from these measures.

Surgical Treatment The general futility of medical treatment in established hypertension made the search for a surgical method altogether natural. A number of our bolder surgeons have devised procedures consisting in the main of cutting off the vasomotor supply to the abdominal arteries and arterioles. Theoretically this seems rational and can be attempted in various ways. It is not my present purpose to go into the history of this subject. Suffice it to say that the principal contributions are from the Mayo Clinic, from Adson and his coworkers, from the Crile Clinic, from Ann Arbor by Peet and his associates, and from the New York Hospital by Heuer and Page. One of the first attempts made to treat essential hypertension surgically was that of George Crile, who about 1910 performed a unilateral adrenalectomy. The operation was followed by a temporary fall in the blood pressure which later rose again to the preoperative level. This temporary success led Dr. Crile to add to the unilateral adrenalectomy

partial resection of the other gland. The blood pressure was affected somewhat more than by the unilateral adrenalectomy alone but it rose again to the disease level.

Crile next attempted to attack the function of the adrenal glands which he held responsible for the hypertension, by denervating the glands in two stages. This had a better effect, the improvement or cure lasting in some cases as long as five years. But recurrences were still common. He therefore extended the operation to include resection of the larger, minor and least splanchnic nerves, but even then results were not what had been expected, so that another approach was chosen, namely resection of the celiac ganglion and denervation of the aorta. The results in 25 instances, chiefly cases of malignant hypertension, have been most encouraging. The operation can be performed under nitrous-oxide-oxygen anesthesia.

Adson and his colleagues at the Mayo Clinic have employed two operative procedures.

- 1 Extensive bilateral section of the ventral roots of the lower thoracic and upper lumbar nerves.

- 2 Extensive subdiaphragmatic sympathectomy, which includes the splanchnic nerves on each side as well as the two upper lumbar ganglia and biopsy or partial resection of the suprarenal gland. It is still too soon to draw definitive conclusions as to the value of these operations but from observations to date Adson, Craig and Brown⁴ prefer the subdiaphragmatic splanchnic resection with removal of the upper two lumbar ganglia and resection of the suprarenal gland.

Page and Heuer⁵ in 17 patients performed section of the anterior nerve roots. They conclude that although the operation has markedly improved the clinical condition of many of the patients studied for periods up to 2½ years its ultimate value in the treatment of hypertension has not been established. In their most recent article⁶ they offer no encouragement.

From reading reports about surgical operations for the cure of hypertension and from my own very limited experience and from reports given to me by my surgical colleagues at the University Hospital, I would conclude that surgery as at present practiced has a long way to go before it justifies itself. But this does not preclude the possibility that some surgical method may be found that can be looked upon as curative. Perhaps we shall go through a stage similar to what occurred in the surgical treatment of hyperthyroidism. There was much criticism of the early operations. But that criticism has vanished before improved technique at operation and better pre- and postoperative care.

The pharmacologist, the biochemist, the clinician, must also continue their intensive studies in the hope of finding the chemical agent that causes vascular spasm. Perhaps the Banting of hypertension has been born.

THE RELATION OF EMOTIONAL STRAIN TO ILLNESS ¹

By G CANBY ROBINSON, *Baltimore, Maryland*

EMOTIONAL strain is an expression which is not readily described by words but is better appreciated by reference to personal experience and probably requires a measure of introspection for its understanding. However, emotional strain seems to be the best expression to describe the condition resulting from social or personal maladjustments which produce annoyance, tension or minor emotional disturbances over prolonged periods. Thackeray says in effect in "Vanity Fair" that it is not the great sorrows, but the little troubles that one daily has to bear that make life hard. It is the troubles that patients have to bear daily that cause emotional strain. It is often related to illness and becomes so closely integrated with it that emotional strain and illness are often inseparable and constitute two phases of a single problem, neither of which can be dealt with effectively alone.

For an appreciation and evaluation of emotional strain, consideration must be given to the personality and physical condition of the patient, the ideas, sensations and symptoms which he can express and describe, and the conditions of his environment, including his social status. Emotional strain is determined by the causes of emotions, the type of person in whom they are aroused and the character of the emotional reactions. This simple formulation is indeed superficial and does not bring into consideration psychopathological states or deep-seated psychic disturbances requiring even "minor" psychoanalysis for their disclosure. It is intended as a formula for the routine use of the practitioner of medicine, in order to reveal and evaluate the emotional components of almost every illness which brings the patient and doctor together.

It is well known by every intelligent person today, layman as well as physician, that many ailments are caused or modified by emotional strain, and many forms of treatment by various sorts of healers are successfully practiced on the basis of this knowledge. Although the private practice of medicine concerns itself, of necessity, with the emotional disturbances of patients, the organization and routine of the general hospital as operated today does not provide a large place for the study of the total individual and of the situations productive of psychogenic symptoms. Nor has it been practical to combine with the thorough and somewhat specialized form of medical education studies that lead to an understanding of the relation of

* Received for publication June 10, 1937.

From the Department of Medicine of The Johns Hopkins University and Hospital.
This paper is from a study supported by a grant from the Rockefeller Foundation.

personal and social problems of patients to their illness, except in psychiatric teaching.

Because of the foregoing considerations, an investigation of the nature and extent of emotional strain as related to illness has been undertaken in the Johns Hopkins Hospital, and measures for its relief, combined with the therapeutic regime prescribed for patients, have been employed. The study has been carried on with almost no attempt to select "suitable" cases, except that most of the patients have been those admitted to the wards and to the general dispensary of the medical service. Of the first 173 patients studied, in 83 or about half, emotional strain was found to form some part of the total clinical picture. In most of these patients organic disease existed and in some of them emotional strain played but a minor part, while in others it was the major factor in understanding the full meaning of the illness and in the treatment of the patient. This study has demonstrated clearly that emotional strain is of more importance as a component of illness in the usual run of hospital patients than had been suspected. The study was undertaken with the conviction that it would reveal certain so-called "accessory factors of health" which were not being considered as fully as might be desirable for the complete medical care of patients, even in a hospital where an unusually high standard of medicine is practiced and where there is a pervading interest in the patient as an individual.

The approach to the patients has been that of a clinician, and the study, diagnoses and treatment by the members of the hospital staff have first been carefully reviewed in order to have a clear conception of the physical status of the patients before the first interview. Patients have then been seen either on the wards or in the office adjoining the dispensary, and their personal and social histories have been expanded and their symptoms further analyzed in the light of the physical findings and laboratory studies.

Whenever any evidence of emotional strain has been revealed, the patients have been further studied in various ways, by home visits, interviews with other members of the family, the study of hospital records of other members of the family when they exist, inspection of working conditions, reports from social agencies and information from various other sources. In this work Miss Josephine C. Barbour, an experienced medical social worker, has been a valuable collaborator. This study is to be reported in detail subsequently.

It is the purpose of this paper to report a single case as an example of emotional strain as related to organic illness, to describe the method of its study and to discuss its significance in relation to treatment. The case is an illustration of how a rather simple social maladjustment may be relieved by a procedure requiring no special technical training and by the application of nothing more than the use of common sense after the cause of emotional strain is revealed.

CASE REPORT

The patient, a 56-year-old white woman laundry worker, was referred to the general medical dispensary from Ophthalmology where she was under treatment for immature cataracts and an error of refraction. She was admitted on January 7, 1936 to the medical dispensary, where she has been studied and followed by Dr. A. Murray Fisher. She complained of poor vision and hoarseness. Her history at this time contained almost no other symptoms. She had lost three or four pounds in weight recently. The hoarseness had been present for nine years, and she attributed it to the atmosphere of the laundry. The history states that she had no headaches, dyspnea, precordial pain or swelling of her ankles, but had nocturia two or three times nightly. She said she did not feel nervous, but on a subsequent visit she said her work was quite hard and that she becomes excited and very nervous at times. She had had an attack of "pleurisy" 11 years previously, but had otherwise had good health.

On physical examination the patient was found to be a fairly well nourished blond woman weighing 118½ lbs., with a flushed face and a rather loud, husky voice who appeared somewhat restless and emotional, with moist skin and a rather coarse tremor of the hands but no exophthalmos. The thyroid gland was palpable but not definitely enlarged or nodular. There was marked pulsation in the episternal notch, and the veins of the neck were engorged. Lungs were clear. Substernal dullness was somewhat widened but there was no cardiac enlargement. A systolic murmur in the aortic area and accentuation of the second aortic sound were noted, with a heart rate of 96. The systolic blood pressure was 210 and the diastolic 120 mm. Hg. The physical examination was otherwise negative. The Wassermann reaction was negative. The basal metabolic rate was plus 23 and a teleroentgenogram showed the heart shadows to be within normal limits, with moderate tortuosity of the aorta. There was a faint trace of albumin in the urine. The phenolsulphonephthalein excretion was 52 per cent in two hours and her hemoglobin was 92 per cent.

The basal metabolic rate was repeated twice at weekly intervals and determined as plus 29 and plus 45, the systolic blood pressure being 235 and the diastolic pressure 130 mm. Hg at the time of the first of these estimates, and 230 and 130 mm. Hg respectively at the time of the second.

A diagnosis of arteriosclerosis with arterial hypertension was made. The evident emotional tension, venous engorgement, marked hypertension and elevated basal metabolic rate led to the conclusion that the patient was threatened with cardiac failure, and a change of occupation and more rest were advised.

The patient was interviewed on February 27 and subsequently a visit to her home was made, the interview being undertaken as a routine measure in a process of sampling dispensary cases without selection because of any apparent problem. She was found to be an employee of the laundry of the Johns Hopkins Hospital where she had worked for nine years. During the past four years she had been quite nervous and emotionally disturbed, somewhat excited and had felt almost constantly "uncomfortable" while at work. Recently she had felt the strain of her work especially, and it now disturbed her so that she became excited and very nervous. During the past three months she had had shortness of breath on exertion especially noticeable on walking up a moderate grade to her work, so that she had been obliged to go to work slowly and by a longer route which avoided the grade. She slept well, but was quite "unhappy" and had a sense of dread on going to work. She had no muscular fatigue, although she stood constantly while at work.

The personal history and social status of this patient indicated that she had experienced severe emotional disturbances in her past life especially connected with her marital history. She had a satisfactory childhood as a member of a large family of seven children who were apparently quite congenial. Married at 21, her first husband was killed in a street accident about a year later, leaving her with an infant,

now a man of 34. She married again two years later, and soon began having difficulties, as her husband proved very unreliable and supported her for a number of years only on court order, leaving her and returning frequently, "as often as fifty times," she thinks. During this marriage two sons were born, now 31 and 28 years old. She was legally divorced seven years after this marriage, and five years later she contracted a third marriage which was also unsuccessful, ending in divorce without issue after about four years. The patient was 40 years old at this time, and at the age of 46 she began to work in the laundry of the Johns Hopkins Hospital, where she has been employed constantly for the past nine years.

The patient lives with one of her married sisters in a comfortable house of which she occupies the third floor. Her sister has been having "heart attacks" for a number of months, and suffers from shortness of breath and swelling of her ankles at times. Her brother-in-law is a pipe-fitter by trade, but has had no regular work for five years, and recently has been employed as a laborer on a WPA project. He owns the house in which they live, but has been unable to pay his taxes for two years. The patient's three sons are unable to help her financially, as one has only part-time work, one is without a job while his wife works, and the third earns but little selling on commission. The patient is therefore entirely dependent on her own earnings.

The patient said that her work in the laundry went well until four years ago when she was promoted to be in charge of the flat ironing machines, with four girl helpers. The patient is unusually conscientious and tries hard to keep the work speeded-up, but is much annoyed by the young women who help her, as they are inattentive and "loaf on the job" when the forewoman is not in sight. The work has increased in volume in recent years, and she does not like it because of the "nervous strain." She said she noticed a complete change in her feelings when she was on a vacation during the summer of 1935, during which time she felt quite well.

From this history it was inferred that the vascular hypertension of the patient was probably related to the various emotional episodes of her married life, which had, we believe, made her especially susceptible to emotional strain. The severity of her hypertension indicated that she should be relieved of emotional strain as far as possible, and it was evident that tension and emotional disturbances were related to the conditions of her work.

In order to observe the patient's working conditions the assistant director of the hospital in charge of personnel was consulted, and a visit with him was made to the laundry. The patient was seen with her helpers, girls of 18 or 20 years who apparently had no particular interest in their work, which consisted in shaking out laundered clothes and placing them on the flat ironing machines. The work had to be kept up to a certain speed, in order to coordinate it with the other processes in the laundry, and the patient seemed to take the full responsibility for this. The superintendent of the laundry said that the patient had recently been failing in her work, as she did not have the necessary authority over her assistants, who teased and laughed at her. He said a change in her work would be helpful to the work of the laundry as well as to the patient. The superintendent agreed to change the work of the patient so that she no longer had the responsibility for other workers, although this could be done only with a reduction of wages of about \$1.50 a week in fairness to other workers. The plan was then explained to the patient, the change being suggested as necessary for her health. After some hesitation and with some sense of disappointment, the patient agreed and her work was changed to sorting clothes on the other side of the flatwork ironing machines. This change was made on March 12, 1936.

The patient was seen on March 19, one week later, and said with enthusiasm that "a miracle has happened, and a big burden has been lifted from me." The feeling of excitement had gone, her neck, she said, no longer swelled and she was no

longer nervous or short of breath Phenobarbital, prescribed one month previously, was discontinued by Dr. Fisher.

The patient has now been followed for over a year since her work adjustment and she has had no return of her previous symptoms. She continues to speak of the effects of the change as "a miracle" and has continued to work steadily, taking no drugs and no longer avoiding the up-grade walk to her work, as it now causes no shortness of breath. She has gained in weight up to 135 lbs. and gives the impression of being a contented, happy person. She no longer appears excited, her voice is not "husky," the face is not flushed and the neck veins are not engorged. Her basal metabolic rate was estimated at plus 20 in May, and plus 4 in December 1936.

The patient has been seen at monthly intervals or oftener, since January 1936 to May 24, 1937, and her blood pressure has been measured sitting up, lying down and after rest, with the object of finding its lowest level.

The blood pressure has shown no appreciable change throughout the period of observation, its lowest level having been 210 systolic and 120 diastolic, while on April 30, 1937 the systolic blood pressure was 245 and the diastolic 135 mm. Hg.

The point of special interest in this case is the almost sudden disappearance of her symptoms when she was relieved of an emotional strain, without any change in her elevated blood pressure. It was natural to attribute her symptoms as primarily caused by the somatic or organic disease from which she suffers, and the adjustment of the conditions of her work was undertaken with the idea that it might have a beneficial effect on her blood pressure. The effects of the work adjustment were, however, different from what was expected, but are instructive, as well as of much value to the patient.

There was a social maladjustment between the patient and the workers she was expected to control and direct. Her own conscientious spirit was in conflict with her young and inattentive assistants, and she did not have sufficient leadership to impose her authority upon them. As this situation had existed for four years with increasing lack of success and with changing assistants, the patient had been under a long emotional strain which had evidently been the main factor in the production of her symptoms. Mayo,¹ in his study of the human problems of an industrial civilization, shows the striking relation of proper social adjustment to the output of industrial workers, and our case suggests that the social adjustment of workers may have a definite relation also to their state of health.

It is interesting to note that among the changes which the patient reports is her ability to walk up the grade on her way to work without dyspnea, while for three months previous to her change of work, she felt forced by her dyspnea to avoid this grade. She also stated that she previously had a feeling of dread on going to work, which has disappeared. These statements are suggestive that the dyspnea was of psychogenic origin, and calls attention to the value of looking for psychic influences in the production of symptoms, even when there may seem to be a satisfactory explanation for them in the existing organic disease.

The change in the basal metabolic rate is also of interest, it having been as high as plus 45 in January 1936, and having been estimated as plus 4 in

December of the same year. The fall in the basal metabolic rate may have resulted from the ability of the patient to attain a more nearly basal state with the disappearance of excitement, or it may have had some other cause.

The relation of an elevated basal metabolic rate to emotion is familiar to all who have worked in this field, but its significance is not clear, although a number of investigations of this subject have been published.

Dunbar² has reviewed a number of these studies and says that the literature is inconclusive because the basal metabolic rate has not been usually correlated with the emotional state of patients but with certain disease groups. Landis³ has studied the effect of emotions on the basal metabolic rate, and finds that an unpleasant emotion, produced by suggestion, is usually attended by a rise in the metabolic rate, and considers this rise as resulting from (a) increased supra-renal or thyroid (?) activity, or (b) increased metabolism of the central nervous system, or (c) increased muscular tonus and incomplete relation. His own experiments are not consistent, as changes in the basal metabolic rate were not always in the same direction or of the same magnitude with the same degree and kind of emotional disturbance. He concludes that changes in metabolic rate cannot be considered as a direct measure of emotional disturbances or cumulative emotional upset. DuBois⁴ discusses the influence of emotion in elevating the basal metabolic rate, and gives some examples to illustrate it, but he offers no further explanation of the phenomenon.

It is evident that our present state of knowledge does not allow a definite interpretation of the change in the metabolic rate that occurred in our patient, but it is of interest to note that there was a well defined decline to a normal level from a distinct elevation with the disappearance of the subjective symptoms after the removal of emotional strain.

This patient is one of many in whom social and personal problems have been found to produce emotional disturbances leading to symptoms, either associated with or without outspoken organic lesions. This patient presented an unusually simple problem which was relatively easy to study and to solve, followed by such striking changes in symptoms as to leave no reasonable doubt as to the relation of cause and effect. The fact that the changes in symptoms occurred without any observable alteration in the outspoken vascular hypertension, indicates the value of studying patients with seemingly unalterable pathological conditions, from the point of view of emotional disturbances. They may be the major cause of distress and disability, and deserve the same careful attention that is given to the organic disease.

It is the daily experience of every practitioner of medicine to see patients whose symptoms are not adequately explained by the findings of the physical examination and laboratory study, especially if a rigid analysis of symptoms in relation to objective findings is made. When a patient presents definite evidence of disease the objective findings outweigh the symptoms of the

patient as the basis for diagnosis and treatment. Attention is focused on symptoms, however, when the objective findings reveal little evidence of disease or when they cannot be related to the complaints of the patient. Then the symptoms are usually recognized as of psychogenic origin. The tedious task of attempting to determine the psychogenic or emotional factors responsible for the symptoms is not usually fully carried out in hospital practice unless they seem of sufficient seriousness to call for a psychiatric consultation, or to lead to the transfer of the patient to the psychiatric service. In many hospitals these desirable procedures are impractical, even for patients with well-pronounced emotional disturbances, and in many cases, patients with symptoms of psychogenic origin are discharged from the wards with encouragement and reassurance, to be followed in the out-patient department or if already there, they are given sedatives, advice and at times referred to the medical social worker. These procedures are often beneficial, but too often the benefits are transient when the underlying causes of emotional strain remain uncovered and unconsidered in the plan of treatment, and patients continue to search for health by many visits to the dispensaries and by various types of special examinations and treatments.

The extent to which harmful emotions may be related to illness is strikingly shown by the extensive literature on the subject that has been collected and reviewed by Dunbar² in her book on "Emotions and Bodily Changes," in which it is indicated that emotional disturbances may affect practically every organ in the body and may play a part in many diseases. Cannon,⁸ whose study of the physiological effects of emotions has continued throughout his many years of research, has recently expressed the opinion that the medical profession has not recognized in a practical way the nervous strain of modern life as a cause of disease, and he emphasizes the importance of regarding man as a "mind-body" unity. He discusses the ways in which success may be achieved in the treatment of emotional disorders by efforts to affect the emotions so that they are no longer harmful in the physiological sense, and will therefore cease to produce "tensions" and turmoil, responsible for many symptoms of illness causing distress and disability.

The study of the emotional components of illness presents many difficulties when an attempt is made to apply to patients the knowledge which the physiologists have developed, but in spite of this, it is the task of the physician to endeavor constantly to gain a better understanding of the effects of emotions in terms of established scientific facts. The case reported in this paper is offered as an example of how causes of emotional strain may be uncovered and removed without perhaps revealing the true, basic nature of its harmful action. Greater insight into these problems will come, however, as practitioners in various fields of medicine come closer in their attitudes and work with the psychiatrists, and when psychiatrists have more opportunity to study the emotional disturbances related to organic disease.

Meyer has for many years emphasized the psychobiological point of view as a field of science which should pervade medicine in all its phases, so that an understanding of the psychic aspects of illness may be progressively developed with the increase of experience and skill of the medical practitioner in any special field he may choose to cultivate. In speaking of the recognition and treatment of visceral and somatic symptoms which spring from mental causes, Meyer¹ says, "These disorders are common enough to make it a responsibility of any physician to learn something about the mental causes and their working. It is not likely that the general practitioner and the internist will be able to do their best without such knowledge. It will have to be acquired by a study of these events when and where they occur, with attention to the situation and to the facts that make reactions excessive."

It is surely true that emotional disturbances must be studied when and where they occur, and it cannot be foretold when or where they are to be encountered. For this reason constant watchfulness is needed by medical practitioners in every field, if emotional strain is to be given its proper evaluation in the production of the subjective evidence of illness, and in medical treatment. This attitude is difficult to maintain, in the wards and outpatient services of the modern hospital. This circumstance does not, however, diminish the importance of emotional strain in relation to illness, but should stimulate further efforts and new methods.

One of the foremost exponents of the study of the patient as an individual, among the internists in this country, who has given much thought and experimentation to the treatment of illness caused by emotional disturbances, is Dr. Joseph H. Pratt. It is hoped that what is written here may in some way be helpful to the cause in which he is much interested. As this paper is to be included in a volume dedicated to him as a *Festschrift*, it is especially gratifying to recall his encouragement and advice regarding the work of which this paper is a part.

SUMMARY

A study of hospital patients with special reference to their social and personal problems has demonstrated that emotional strain frequently causes an important component of illness, deserving consideration in diagnosis and treatment.

A patient with an apparently unalterable organic disease is reported whose symptoms disappeared with the relief of emotional strain.

The significance of this case as an example of psychogenic symptoms in organic disease and the methods of study and treatment used are discussed.

The need of greater consideration of the patient as a total individual, in order to gain a better understanding of emotional disturbances as related to illness in hospital practice is emphasized.

THE LIPID AND CHOLESTEROL CONTENT OF THE BLOOD OF PATIENTS WITH ANGINA PECTORIS AND ARTERIOSCLEROSIS

By DAVID DAVIS, M D , BEATRICE SILRN, B A , and GERSON
LLSNICK, M D , *Boston, Massachusetts*

THE present study of the blood cholesterol and lipids in patients with angina pectoris of arteriosclerotic origin was prompted by the general interest in the relationship of cholesterol metabolism to the pathogenesis of arteriosclerosis. No systematic study of the cholesterol and lipid constituents of the blood in patients with coronary sclerosis is available in the literature.

There are, however, some studies on the cholesterol concentration in the blood of patients with arteriosclerosis. Bachmeister and Henes,¹ in 1913, after a study of 13 patients with arteriosclerosis and of nine normal individuals, stated that patients with atherosclerosis in the stage of development showed an increase in the blood cholesterol, but that no deviation from the normal was found when the process was stationary. The evidence presented was inconclusive. Weltmann,² without giving details, also reported increased values in 11 out of 12 patients with arteriosclerosis complicated by other diseases. It was his impression that hypercholesterolemia ran parallel, to a certain degree, with the severity of the arteriosclerosis. Denis,³ in 1917, unconvinced because of the number and variety of conditions in which abnormal cholesterol values were reported, studied the cholesterol in 14 patients with atherosclerosis and compared their values with those of 20 normal individuals. The values of the normals varied from 167 mg to 225 mg per cent, and were essentially in agreement with Bloor's normal figures⁴ for the same method. Five of the 14 patients with arteriosclerosis showed values of 250 mg or above, these five patients had cardiac disease or nephritis. One of these had angina pectoris and a cholesterol value of 268 mg. Gorham and Meyers⁵ also studied 10 patients with atherosclerosis and compared their values with those of 14 normal individuals. The values of the atherosclerotic group varied from 160 to 230 mg, those of the 14 controls, from 130 to 190 mg per cent.

In the reports mentioned, no careful consideration was given to the criteria employed in the selection of patients with arteriosclerosis. Mjasnikow⁶ in 1926, presented more convincing evidence that he was dealing with arteriosclerosis. He used the following criteria: orthodiagraphic evi-

* Received for publication April 9, 1937.

From the Medical Research Laboratories, Beth Israel Hospital, and the Department of Medicine, Harvard Medical School, Boston.

dence of enlargement of aorta in the absence of syphilis and hypertension, aortic murmurs, and clinical symptoms of coronary disease. He employed two colorimetric procedures^{7,8} and finding a constant difference between them recorded his values with one, the method of Grigaut. In 16 patients with arteriosclerosis, the blood cholesterol was elevated in every instance, 12 of these patients had angina pectoris. For control data he relied on the normal values for the method used and the results in his non-arteriosclerotic patients. These normal values varied from 120 to 170 mg, those in the arteriosclerotic group, from 190 to 440 mg. In a second group of 25 patients in whom the diagnosis of arteriosclerosis was less certain, there were elevated values in 10 instances. Koulikov, Veiland and Tarnopolskaja⁹ in 1931, studied cholesterol values in patients with cerebral arteriosclerosis, and noted increases in some instances. Their data, however, are too incomplete to permit proper evaluation.

Stepp¹⁰ on the other hand, without offering evidence, stated that he was unable to find any abnormality of the blood cholesterol in patients with arteriosclerosis. Andes, Kampmeier, and Adams¹¹ came to a similar conclusion, these latter authors studied the blood cholesterol in 35 healthy medical students and compared values with those of 31 negroes, 16 of whom showed atherosclerosis. Of these 16, the ages in 11 varied from 20 to 30 years, and vascular disease was judged by compression of brachials, and in some instances, the condition of the dorsalis pedis. Elliot and Nuzum¹² in a study of the cholesterol values in hypertension incidentally estimated the degree of arteriosclerosis in their patients, by considering the condition of peripheral arteries, fluoroscopy of the aorta, and ophthalmoscopic examination of the fundi. In 19 patients with moderate or advanced arteriosclerosis, the blood cholesterol was essentially the same as in their controls.

In 1935, Duff¹³ summed up the published data on the subject as follows: "It is sometimes stated that hypercholesterolemia is regularly associated with arteriosclerosis in man, but such statements are based on a literature much of which has no direct bearing on the question. Some publications which are frequently referred to in this connection have nothing to do with arteriosclerosis as such, but are concerned with various other diseases in which hypercholesterolemia is known to occur and with which arteriosclerosis may be associated. Whatever may be the truth of the matter, it is obvious that these data prove absolutely nothing regarding the occurrence of hypercholesterolemia in association with anatomic lesions of the arteries."

Recently, Lande and Sperry,²⁹ aware of the difficulty in recognizing arteriosclerosis clinically, attacked the problem by studying the blood lipids shortly after sudden death. The total cholesterol was then compared with the lipid content and the degree of gross atherosclerosis of the aorta. No correlation between the level of blood cholesterol and the degree of atherosclerosis was found. Many abnormal values due apparently to such factors as (1) infection during the few hours following the accident and (2) he-

molysis, were excluded, and reliance was placed on the constancy of the ratio of free to total cholesterol as a guide to the accuracy of values obtained. In a study of this kind, however, there are two possible sources of error that would not necessarily alter the free to total cholesterol ratio: (1) dilution of blood serum following hemorrhage (death in most instances followed automobile accidents), and (2) concentration of blood serum attending shock with loss of body fluids. Further, the range, 82 to 446 mg per 100 c c, of values obtained on these bloods drawn shortly after sudden death was greater than the distribution usually accepted as normal.

In the present study, attention was directed to the following considerations: (1) methods of analysis, (2) selection of patients with angina pectoris, (3) selection of control subjects, (4) statistical treatment of data.

Methods There have been several recent criticisms of the colorimetric methods for the determination of blood cholesterol^{14,15}. For this reason the gravimetric method of Man and Peters¹⁶ in addition to the colorimetric method of Meyers and Wardell¹⁷ with apparatus for continuous extraction described by Ling¹⁸ were used in this investigation. The values obtained by both cholesterol methods on the same blood were compared in 50 instances¹⁹. In general a fairly close agreement was noted. The average deviation of the colorimetric determinations from the gravimetric was plus or minus 8 per cent. Free cholesterol was precipitated with digitonin from the alcohol ether extract before saponification. The precipitates were weighed on a micro balance. Fatty acids and phospholipids were determined by the methods of Stoddard and Drury, and Fiske and Subbarow respectively, as modified by Man and Gildea²⁰. The fatty acids were determined as milli-equivalents and translated into milligrams by multiplying by 277, the average molecular weight of the fatty acids as they usually occur in blood. Measurements were made in duplicate. Venous blood was drawn with minimum stasis from patients in the post-absorptive state. The basal metabolic rate was determined in duplicate with the Collins, Benedict-Roth apparatus and results calculated according to the Aub-DuBois²¹ standards.

Selection of Subjects A large group of patients with angina pectoris and coronary disease was available in this clinic. Most of these patients were followed by Drs. Riseman and Brown and the diagnoses of angina pectoris were confirmed by exercise tolerance tests²². The duration of the disease, in every patient on whom lipid studies were made, was more than one year. Approximately one-third of the group gave a history consistent with cardiac infarction in the past. Patients with rheumatic and syphilitic heart disease were excluded. All were ambulatory, and at the time blood samples were taken, they were not suffering from any of the usual cardiac complications, such as acute coronary thrombosis, or circulatory failure. Those selected for this study were likewise free from other complications that might alter the lipid metabolism, such as myxedema, diabetes, or

nephritis There had been no departure from their usual diets, and no obvious changes in weight The majority of patients had been on some form of medication such as aminophyllin or small doses of nitroglycerine Ten of the 59 patients studied were female The ages in the entire group varied from 38 to 69 with a mean of 55 years

Selection of Controls The selection of controls presented a problem To insure a low incidence of atheromatosis, one would naturally choose very young adults On the other hand such a selection might be held unsatisfactory because of the possibility of lipid and cholesterol values increasing with age It has been shown, however, that the distribution of the lipid values in older individuals is the same as in young adults²³ Our controls were healthy individuals chosen from among the students, physicians, and workers of the hospital Subjects in both lower and upper age groups were included The ages in this group of 54 subjects varied from 18 to 69 with an average of 34 years In 28 of these in whom more complete blood lipid studies were made, the average age was 42 and 14 of these were above the age of forty-five

RESULTS

Total Blood Cholesterol The cholesterol values by the colorimetric method in 59 patients with angina, and in 54 normal controls are shown in table 1 More values in the higher range are noted in the angina group Thirty-five patients, as against 16 in the control group, showed values above 250 mg The highest cholesterol in the control group was 287 mg while in the angina group there were 13 patients with values above 287 mg Figure 1 shows the distribution of these values expressed in per cent of total cases The values obtained in patients with angina pectoris are seen to taper off slowly with a spread considerably beyond the control values The mean for the angina patients is 260 mg \pm 6.9, the mean for the control group 218 mg \pm 5.4, the difference 42.0 mg \pm 8.8 (Table 3)

Table 2 gives the cholesterol values by the gravimetric method in 32 patients with angina pectoris and in 22 controls More of the values in the angina group, as measured by this method, are also in the higher range Eighteen of 32 values in patients with angina, or 56 per cent, were above 250 mg while in the normal group only five or 22 per cent of 22 values were above 250 mg There were 12 values in the anginal group above 282 mg, the highest normal cholesterol The distribution of these values is shown in figure 2 The mean cholesterol for the angina group is 259 mg \pm 10.2, the mean for the control group 219 \pm 8.7, the difference, 40 \pm 16.7 (Table 4)

Free Cholesterol A comparison of the values for free cholesterol in 31 patients with angina and 16 normal controls (table 2) shows again a higher average value for the former Twenty-one of the 31 values were 80 mg or above, as against five out of 16 normal controls above 80 mg

There were no values in the control group above 89 mg while in the anginal group there were 13 values above 89 mg. The comparative distribution is seen in figure 3. The mean for the control group is $70.2 \text{ mg} \pm 3.5$, the mean of the anginal group is $86.4 \text{ mg} \pm 2.5$, the difference 16.2 ± 4.3 (Table 3).

Phospholipids Table 3 shows the distribution of the phospholipids as milligrams lipid phosphorus in 34 patients with angina and in 28 normal controls. Twenty-six of 34 values in angina were above 10.0 mg while but 10 of the 28 control values were above 10.0 mg. The highest normal value was 12.2 mg while in the angina group there were seven values above 12.2 mg. Figure 4 shows the distribution of these values, the differences are obviously significant. The means for the anginal and control group are $11.2 \text{ mg} \pm 0.26$, and 9.4 ± 0.30 respectively, with a difference of 1.77 ± 0.40 (Table 3).

FIG 3 Distribution of free cholesterol in 31 patients with angina pectoris and 16 normals

Fatty Acids A comparison of the fatty acid values in 35 patients with angina, and in 28 normal controls is shown in table 3. Figure 5 shows a tendency toward higher values in the patients with angina for this lipid also. The differences are not so marked as in the case of cholesterol and phospholipids. The mean for the normal fatty acids is $369 \text{ mg} \pm 18.1$, for the anginal group, $429 \text{ mg} \pm 13.7$, the difference 60 ± 22.7 .

Summary of Statistical Analysis of Data In table 3 the values of the several lipid constituents of the blood of patients with angina are com

* When two or more measurements were made in a given patient, the average value was utilized in computation

FIG 4 Distribution of lipid phosphorus in 34 angina pectoris patients and 28 normals

pared with the values in the normal control group. The column M gives the arithmetic mean of the determined values. The column S gives the standard deviation of the series calculated according to the formula $S = \sqrt{\sum D^2 / N - 1}$ where $\sum D^2$ is the sum of the squares of the differences of the individual values from the mean value and N is the number of cases. The column S_m gives the standard deviation of the mean and is equal to S/\sqrt{N} or $\sqrt{\sum D^2 / N(N-1)}$. The column D gives the difference between the mean of the angina group and the normal group. The column S_d gives the standard deviation of that difference which is equal to the square root of the sum of the squares of the standard deviations of the

FIG 5 Distribution of fatty acids in 35 angina pectoris patients and 28 normals

respective two means. The column D/S_d gives the ratio of the difference to its standard deviation. In general, values of the ratio above two are considered probably significant and values above three practically certainly significant. Column P gives the probability of a difference as great or greater than the one listed, being due purely to chance. A value of P of 1.0 indicates a probability of 1 per cent or one chance in 100 of the difference being due to a sampling error.

The Normal Values Man and Gildea²⁴ recently studied the blood lipid values in a group of normals. In 76 healthy individuals the mean of the cholesterol values was 196.8 ± 40.22 mg lower than the mean in our control series. This difference is probably significant. Their phospholipid

values were close to ours with D/S_a less than one, although our values were 3 to 5 per cent higher

Gildea, Kahn, and Man²⁵ make the interesting observation that in males the normal lipid values are higher in those with a pyknic and lower in those with a leptosome type of constitution. The pyknic type refers to the stocky individual of short or middle height, rounded figure, broad face and large rounded head on a short massive neck, the leptosome or asthenic, to those with opposite attributes such as greater development of extremities, narrower trunk, longer neck and oval face. The incidence of pyknic types in our small group of 22 normals was slightly higher than in their normals. The proportion of Jews was small in their normals, whereas in our series they comprised half. The cholesterol values of 13 of these Russian-Jewish normals gave an average of 235 mg, the average of nine Gentiles was 193 mg. Eliminating one value of 101 mg in the latter group, which was extremely low, the average was 212 mg. The ratio of the difference between the two means of Jew and Gentile (with the low value of 101 eliminated from the Gentile group) to its standard deviation is 1.69. The probability of such a deviation being due purely to chance is 9.1 out of 100. The phospholipid difference in 14 Jews and 11 Gentiles was similar $D/S_D = 1.74$, and the same was true of the fatty acids to a lesser degree, $D/S_D = 1.43$. These differences raise the possibility of differences due to race. In the group, however, of 59 patients with angina and 54 normal controls which we studied by the Meyers and Waidell method there were three and 14 Gentile subjects respectively. Racial influence, if it exists, was therefore unimportant in our comparisons.

It will be noted that the controls include subjects in both the lower and upper age groups. It has been shown by Page, Kirk, Lewis, Thompson, and Van Slyke²³ that blood lipids and cholesterol values of individuals in different age groups are essentially the same. Our data, as far as they go, are in conformity with this important finding. For example, the average cholesterol of 27 normal individuals below the age of 30 is 215 mg (table 1) as compared with an average of 218 mg for the entire group of fifty-four. Also in nine normals above the age of 50 (table 2) the mean cholesterol measured by the gravimetric method was 214 mg as compared with 219 mg for the entire group of twenty-two. It is of further interest in this connection that measurements made in a few normal subjects at intervals over a period of approximately three years reveal an individual tendency to maintain a rather constant general level of blood cholesterol.

The Inter-relationship of Lipid Fractions, the Ratio of Free to Total Cholesterol. The inter-relationship of the lipid constituents can be seen in table 2. Although there are a number of exceptions, the lipid fractions in the same individual, either normal or angina pectoris, are in a general way proportional to each other. The cholesterol and phospholipid values are more closely proportionate to each other than either of these to the

fatty acid values. A similar proportionality was found in well treated diabetic patients by Man and Peters¹⁶ and in malnutrition by Man and Gildea³⁰. The parallelism of cholesterol and phospholipid values in their series was closer than in ours.

The ratio of free to total cholesterol (figure 6) appeared to be fairly constant for both the normal and the angina groups with a free cholesterol value ranging from 27 to 44 per cent of the total. The mean of the free cholesterol percentages of the totals in the normal group is 32.3 per cent, in the angina group 33.4 per cent. These findings agree fairly closely with those of Page, Kirk, Lewis, Thompson, and Van Slyke²³ who found in normals that the mean of the free to total cholesterol ratios was approximately 37 per cent. In a recent study of 91 healthy adults, Sperry²⁶ using his own method found an average ratio of 26.9 per cent with a maximum of 30.1 per cent and a minimum of 24.3 per cent.

FIG 6 The ratio of free to total cholesterol in 32 patients with angina pectoris and in 16 normal controls

Relation to Basal Metabolic Rate and Hypertension To rule out any possible influence of a preponderance of low metabolic rates in one group or another, the average metabolic rates were considered (table 1). The average basal metabolic rate for 52 patients with angina was minus 8 per cent, for 32 controls minus 13 per cent. The higher incidence of basal metabolic rate values of minus 20 per cent or below in both groups is noteworthy in the absence of clinical hypothyroidism.

In table 2, the presence and degree of hypertension in the patients with angina pectoris are recorded. One plus represents a systolic pressure of 160

to 180 mm or a diastolic of 95 to 100 mm, two plus, a systolic of 180 to 200 mm, or a diastolic of 100 to 110 mm, and three plus, a systolic above 200 or a diastolic above 110 mm of mercury. It will be observed that only four of 34 patients showed moderate or marked hypertension (table 2). Hypertension, generally mild, was present in 13 patients or in 38 per cent. The average cholesterol and phospholipid values of these 13 patients were 266 mg and 11.6 mg respectively. The average cholesterol of 18 and the average phospholipids of 20 patients, both groups without hypertension, were 251 and 10.8 mg respectively. It is obvious that these slight differences are not significant and that the elevated values obtained were not related to hypertension.

DISCUSSION

An analysis of the data presented indicates that the blood lipids are frequently elevated in patients with angina pectoris of atherosclerotic origin. Increases were noted in all the lipid fractions: cholesterol, free and total, lipid phosphorus and fatty acids. These increases are probably more significant than is apparent, in view of the fact that an appreciable percentage of normals have or will develop coronary atherosclerosis. The differences noted obviously applied only to groups. As evidenced in figures 1 to 5, there was considerable overlapping of the values in the patients with angina and those in the control group. It is apparent that lipid values are normal in a large group of patients with angina pectoris. The occurrence of definitely elevated values in some, however, suggests that the lipid and cholesterol metabolism is disturbed either primarily or secondarily in at least a certain group of patients with angina pectoris.

When rheumatic and syphilitic heart diseases are excluded, angina pectoris is, in the majority of instances, associated with coronary atherosclerosis. Stocks²⁷ states, for example, that a reasonable and conservative estimate of the incidence of atherosclerosis of the coronary arteries in patients with angina pectoris is 85 per cent. To obtain further data on this question an analysis was made of 36 necropsy protocols where angina pectoris of arteriosclerotic origin was the clinical diagnosis. Thirty-two or 89 per cent of these patients showed a moderate or marked degree of atherosclerosis of the coronary arteries.

Although there are notable exceptions, coronary atherosclerosis is usually associated with generalized changes of the same kind in the aorta and other vessels of the body. Saphir, Priest, Hamburger, and Katz,²⁸ for example, found moderate or severe general arteriosclerosis in every one of a group of 34 patients with coronary arteriosclerosis and infarction. This would imply that the lipid findings in angina pectoris are in some measure true for general arteriosclerosis.

CONCLUSION

The average cholesterol, free and total, lipid phosphorus and fatty acids of a group of patients with angina pectoris of atherosclerotic origin were found higher than in a group of control subjects. There was considerable overlapping with the values of many angina patients in the normal range. A small group with angina pectoris showed values well above the highest normal value.

We wish to thank Marie C. Volk and Edward S. Glasser for their technical assistance in this investigation.

THE SIGNIFICANCE OF CARDIAC ENLARGEMENT CAUSED BY ARTERIOVENOUS FISTULA *

By WILLIAM B PORTER M D , F A C P , and JAMES P BAKER, JR , M D ,
Richmond, Virginia

FOLLOWING the establishment of a fistulous connection between an artery and a vein, there occur changes in the dynamics of the circulation which result in varying degrees of cardiac enlargement and of dilatation of the involved artery and vein proximal to the fistula. The extent of the changes depends mainly upon the size of the vessels involved and the caliber of the fistula ¹

In 1924 Holman ¹ expressed the opinion that the dilatation of the proximal artery and vein was an adjustment mechanism for the accommodation of the increased volume of blood flowing through the artery-vein fistulous system. These conclusions are tenable and universally accepted. The causation and the significance of the cardiac enlargement which occurs in association with the vascular changes remained a debatable problem.

From a series of 11 cases of acquired arteriovenous fistula four have been selected for special study because we felt they offered opportunities for the acquisition of fundamental data relevant to the significance of the cardiac enlargement.

1 In three instances the femoral vein and artery were involved at approximately the same anatomical point. The popliteal was involved in the fourth.

2 In one instance the fistula had existed for five weeks, in another eight months, in the third three years and seven months, and in the fourth 21 years.

3 The location of the fistulae made it possible to study the venous pressure and the velocity of venous flow proximal to the fistulous connection.

METHODS USED

All physiologic studies were made three to four hours after the last meal, the patient remaining in bed on these days. The venous pressure was measured by direct venipuncture, using the apparatus and technic of Moritz and von Tabora ². Measurements of the velocity of blood flow were made with the use of the cyanide method of Robb and Weiss ³.

* Presented in abstract at the meeting of the Association of American Physicians, May 4 and 5, 1937. Received for publication June 19, 1937.

From the Department of Medicine, Medical College of Virginia, Richmond, Virginia.
The operations were done by Dr I. A. Bigger, Chief of the Surgical Staff, Hospital Division, Medical College of Virginia, Richmond, Virginia.

The heart size was determined by the use of teleroentgenograms. These were standardized to constant chest diameters and the position of the diaphragmatic level. The prediction formula of Hodges and Eyster⁴ was used in calculating normal transverse cardiac diameter.

CASE REPORTS

Case 1 S. B., a negro laborer, aged 45, five weeks previously had received a bullet wound in the upper right thigh. He stated that he was working as a laborer 10 days after the accident without subjective complaints or impaired function of the involved limb.

Physical examination. A well developed negro man in a normal state of physical fitness. The local phenomena of an arteriovenous fistula were present at the apex of Scarpa's triangle on the right side, indicating a fistulous connection between the right femoral artery and vein.

| | | Fistula opened | Fistula closed |
|---------------------|------------------|----------------------------|-----------------------------|
| Blood pressure | | systolic 130, diastolic 65 | systolic 150, diastolic 100 |
| Pulse rate | | 79 per minute | 62 per minute |
| Vital lung capacity | predicted normal | 5,360 c c | |
| | actual | 5,180 c c | |

Electrocardiogram normal, no change following operation. The physiological studies and heart size data before and after operation are shown in figure 1.

Case 2 A. H., a white farmer, aged 32, had received a bullet wound in the upper left thigh three years and seven months previously. He stated that he resumed his farm work two weeks after the accident. He noticed a thrill and swelling over the femoral area a few days after receiving the wound. For the past seven months there had been some swelling of the left foot and ankle. During cold weather this foot became numb and there was aching in the calf muscles of the left leg if he walked rapidly up grade. The subjective complaints were not sufficient to stop him from his work. He came for relief of the functional impairment and swelling in the left leg.

Physical examination. A well developed man in a normal state of physical fitness. The local phenomena of an arteriovenous fistula were present 2 cm. below the apex of Scarpa's triangle on the left side indicating a fistulous connection between the left femoral artery and vein. There was slight pitting edema of the left ankle.

| | actual | 5,300 c c | |

Electrocardiogram normal, no change following operation. The physiological studies and heart size data before and after operation are shown in figure 2.

Case 3 A. G., a white boy, aged 16, had received a bullet wound in the left popliteal space eight months previously. Two weeks after the accident he resumed his usual physical activities, consisting of work on a farm and playing baseball whenever he was not otherwise engaged. His only complaint was fatigue and aching of the left leg after strenuous exercise.

Physical examination. A robust well developed boy in a normal state of physical fitness. The local phenomena of an arteriovenous fistula were present in the left popliteal space indicating a fistulous connection between the left popliteal artery and

| Pulse rate | 90 per minute | 76 per minute |

Electrocardiogram normal, no change following operation The physiological studies and heart size data before and after operation are shown in figure 3

Case 4 C B, a negro farmer, aged 58, had received a bullet wound in the right thigh 21 years previously Following the accident he remained in bed for 10 days When the dressing was removed he noticed upon touching the upper part of the thigh a peculiar purring sensation which he states has continued and become more distinct Since the healing of the wound he has worked regularly as a farmer with no discomfort except for the occurrence of cramps in the calf muscles of the right leg There had been swelling of the right foot and leg for four years He came for relief of the functional impairment and swelling of the right leg

Physical examination A well developed and nourished negro man lying comfortably in bed without subjective complaints The local phenomena of an arteriovenous fistula were present 3 cm below the apex of Scarpa's triangle on the right side indicating a fistulous connection between the right femoral artery and vein There was a moderate degree of brawny edema up to the upper third of the right leg The vessels above the fistula were greatly enlarged as far as they were palpable The jugular bulb on the right side was markedly dilated but there were no pulsations above the auricular level There were no phenomena indicating heart failure of the congestive type

DISCUSSION

It is evident from these studies that cardiac dilatation is the principal factor concerned in the increase in cardiac size in arteriovenous fistula The amount of actual hypertrophy is determined mainly by the duration of the fistulous connection (figure 5)

Lewis and Drury^{1, b} concluded that the enlargement of the heart was primarily and chiefly a dilatation due to a deficient nutrition of the heart muscle, consequent on a fall of the mean arterial blood pressure occurring in arteriovenous fistulae They did not believe there was increased circulating blood volume for in experiments on dogs an anastomosis of an artery and vein did not increase cardiac output unless there was a rise in general venous pressure, and no rise in general venous pressure occurs in arteriovenous fistulae without heart failure Recently Laplace⁵ and Quattlebaum⁶ have expressed opinions in agreement with that concept of the pathogenesis of cardiac enlargement

It is an established physiologic principle that the minute volume of cardiac output is dependent primarily upon the volume of the return flow to

FIG 5 Reducible and irreducible cardiac enlargement related to the duration of the arterio-venous fistula

the right auricle, and the force of cardiac contraction is so perfectly adjusted to the quantity of blood which flows into the auricle from the veins that no stasis occurs with a rise of general venous pressure unless heart failure ensues

The observations made on these patients show that all the factors which can increase the volume of return flow to the right heart operate in arteriovenous fistulae, and in these patients without heart failure there was no rise of general venous pressure

That the dilatation of the heart is not due to a nutritional deficit of the myocardium is evident from the cases here studied. It is inconceivable that a nutritional factor could be responsible for so marked a degree of reducible dilatation continuing for a long period * and without the development of heart failure in men engaged in active physical labor. Furthermore, Green⁷ has shown that in arteriovenous fistulae the decrease of coronary blood flow induced by a lowering of diastolic blood pressure is to a considerable extent mitigated by an increase in coronary blood flow during systole resulting from a relative lowering of the systolic peripheral coronary resistance in relation to aortic pressure. Through peripheral vascular constriction a normal mean blood pressure may be approximated and this, operating in conjunction with the augmented systolic coronary circulation, may result in an increase of coronary flow to or even above a normal minute volume.

The observations made on these patients indicate that the cardiac enlargement occurring in arteriovenous fistulae results from the following changes in the dynamics of the circulation

1 (a) There is great increase in cardiac filling due to acceleration of the velocity of blood flow and increase of effective venous pressure in the involved vein and anatomically associated tributaries proximal to the fistulous connection

(b) With adjustment dilatation of the artery and vein the rate of blood flow and the pressure in the vein decrease while the cross section of the column of the returning current increases

(c) The enlargement of the artery and vein in the fistulous circuit and the increase in cardiac size are primarily an adjustment dilatation. Cardiac hypertrophy is responsible for only a small part of the increase in cardiac size

2 An extreme degree of reducible cardiac dilatation, 21 cm to 15.2 cm, can exist over a prolonged period (21 years) with the occurrence of only a minimum amount of cardiac hypertrophy and without the development of heart failure. This is not in agreement with the concept of a myocardial nutritional defect as the factor responsible for the changes in cardiac size

* In this connection the observations made on Case 1 are of interest. The femoral artery was temporarily occluded by ligature. Within 24 hours the cardiac dilatation had reduced from 15.5 cm to 13.4 cm. Due to the ischemic symptoms developing in the foot, the ligature was removed. Within 24 hours thereafter the heart again measured 15.5 cm.

CONGENITAL ADHESIONS OF THE GALL- BLADDER ¹

By LESTER R. WHITAKER, M D , F A C S , *Boston, Massachusetts*

ABNORMAL peritoneal attachments to the gall-bladder are more common than inflammatory adhesions. Though often described these congenital adhesions ¹ are not generally recognized, so strong is the obsession in the medical profession that all disturbances of the gall-bladder are inflammatory in origin. Yet, it should be obvious to the careful observer that these sheets of tissue, running from lesser omentum to gall-bladder, duodenum and colon, are simple folds of peritoneum having definite relations, definite structure, and regular arrangement of vessels. They cannot possibly be the result of inflammation. Often with these attachments there is no evidence of a past infection of the gall-bladder, in fact, many times the vesicle appears normal.

Inflammation as a result of infection has been over emphasized in pathological conditions of the gall-bladder—considered primary to everything—especially to gall-stones. Anatomical, mechanical and metabolic factors have been neglected. Even cholesterosis confined to the mucosa of the gall-bladder has been attributed to infection, though this is no more likely to be true than with atherosclerosis. It is probable that they are both degenerative diseases, from toxic or metabolic disturbance, with inflammatory effects.

There are two ways of determining whether or not the peritoneal attachments under discussion are congenital or inflammatory adhesions. The first, and most important, is their anatomical relations. The second is lack of evidence of inflammation in the gall-bladder itself.

Embryologically, the development of abnormal peritoneal attachments of the gall-bladder appears fairly simple. The primitive digestive tube has an anterior and a posterior mesentery. In rotation of the stomach the posterior mesentery becomes the greater omentum, and the anterior, the lesser omentum. In the anterior mesentery a bud grows out from the enteric tube to form the liver, bile ducts and gall-bladder. Ordinarily the anterior mesentery stops at the common bile duct and portal vessels, but it may be more extensive and run from the common duct laterally over to the gall-bladder, down to the duodenum, and to the hepatic flexure of the colon—even to the right lobe of the liver and to the lateral and posterior abdominal walls, perhaps closing the foramen of Winslow. There may be

* Received for publication April 16, 1937

From the Department of Anatomy, Boston University School of Medicine and the Surgical Clinic of Massachusetts Memorial Hospitals, Boston, Mass.

much or little of this anterior mesentery, from a slight band of tissue running from the lesser omentum across to the cystic duct and down the front of the gall-bladder, to the extensive sheet of tissue described above. On this sheet may become a loose veil with a mesentery to the gall-bladder, which means simply that the gall-bladder is enfolded and supported in the tissue. The sheet may be closely adherent to the gall-bladder over its surface or there may be two separate sheets, one running to the medial and one to the lateral margin of the vesicle, usually attaching to the liver on either side. The sheet may pass over the gall-bladder without attachment. The tissue may be absent above and below, leaving only a band from the lesser omentum across the duodenum to the anterior surface of the gall-bladder. It may be supplemented by another distinct band to the hepatic flexure of the colon. In all these types the general relations are the same except that different parts of the sheet of tissue may be missing.

Meyers and Bloom² in 1933, made a study of these congenital peritoneal adhesions in the upper right quadrant of the abdomen, but while stating that these definite structures described were not of inflammatory origin, they have contributed to the general misunderstanding with regard to their nature by the terms, "periduodenitis" and "pericholecystitis" or "essential periduodenitis". Because of confusion of terms and the frequency of this abnormality, surgeons may be led to make false operative diagnoses in many cases.

A resume of literature by Meyers and Bloom shows that different authors have found, on the average, 20 per cent of abnormal peritoneal attachments about the gall-bladder and duodenum in apparently normal individuals. In 54 cadaver and autopsy specimens they themselves found membranes in 54 per cent. Only 5 per cent showed inflammatory adhesions.

In 51 cadavers examined by the writer at the Boston University School of Medicine definite abnormal peritoneal attachments to the gall-bladder were present in 45 per cent. All of the gall-bladders with these congenital adhesions appeared thin-walled and normal. All except one were in male cadavers. (There were not more than five or six females among the 51 subjects.) This is another fact which weighs against inflammatory origin, since cholecystitis is more common in the female.

Among 100 patients upon whom cholecystectomy was performed by me at the Massachusetts Memorial Hospitals 18 showed definite abnormal peritoneal attachments to the gall-bladder. Fifteen of these 18 patients were women. From a statistical point of view it is doubtful that sex is significant in this condition.

Following is a summary of the anatomical arrangement of congenital peritoneal adhesions in 23 cadavers and in 18 patients.

Twenty-three of 51 cadavers examined had definite congenital adhesions to the gall-bladder and duodenum. In this series the arrangement typical for such attachments prevailed, that is, a sheet of tissue running from the lesser omentum to the gall-bladder, along its border toward the fundus,

with bands running across the duodenum and to the hepatic flexure of the colon. In one case there was a small band about 2 cm. in width from the ampulla of the gall-bladder across the duodenum. All the others had attachments of at least two-thirds the length of the gall-bladder, three of them from the gall-bladder to the duodenum alone, and the other 20 from the gall-bladder to the duodenum and hepatic flexure of the colon. In two of these there were extra strands of peritoneal tissue running from the first and second parts of the duodenum up to the liver, but *in no case was any constriction of the duodenum produced*. In four of the 23 cases the foramen of Winslow was closed. One case with the extensive type of attachment described had, in addition, a short mesentery of the gall-bladder. Jackson's membranes were present in three, which does not show a large relationship with congenital peritoneal adhesions elsewhere. In two cases outside this series the author observed an extensive peritoneal attachment of the hepatic colon to the right lobe of the liver laterally, with none to the gall-bladder. In one other case an attachment ran from the liver to a point at a considerable distance along the transverse colon.

All the gall-bladders of this series in cadavers were thin-walled and apparently not inflammatory. There was one female among 22 males. The instances of inflammatory adhesions in the whole number of 51 were not recorded, but I am sure that there were not over 10—a much lower percentage than that of congenital adhesions.

In 18 patients from a series of a hundred cholecystectomies by the author at the Massachusetts Memorial Hospitals a greater variety of abnormal attachments prevailed.

In five cases there was a peritoneal sheet running the whole length of the gall-bladder, in four this was connected with the duodenum, and in two with the hepatic colon. *In one of these there was moderate constriction of the second portion of the duodenum.* The foramen of Winslow was closed in two.

In four cases there were small attachments running from one-third to one-half way down the gall-bladder. In all of these a band passed over the first or second part of the duodenum, and in one the foramen of Winslow was closed.

In two cases there was a loose veil of tissue running over the whole gall-bladder and attached to duodenum, colon and liver. In these two cases definite mesenteries of the gall-bladder were present. *In one of them there was a short strand running from the duodenal cap to the liver, producing some tension.* In both, the foramen of Winslow was closed.

In five cases there were sheets of tissue running across the gall-bladder at varying distances below the fundus, and attaching to the liver and posterior abdominal wall laterally. Four of these *showed bands running across the duodenum, two of which produced moderate constriction.* In three cases there were attachments to the hepatic flexure of the colon, and in three of the five the foramen of Winslow was closed. The appearance of one

case was described as a "sort of blanket thrown over the gall-bladder with the head and chest sticking out" In another case there was a second sheet running to the postero-lateral margin of the gall-bladder The description here was, "the fundus of the gall-bladder looked almost like the head of a doll protruding from between the upper and lower blankets"

In one of these cases an unusual situation prevailed I quote from the operative note, "Running from the lesser omentum and the first part of the duodenum across the fundus of the gall-bladder to the liver and then on to the second portion of the duodenum and hepatic flexure of the colon was a thin sheet of peritoneum-like tissue This sheet of tissue ran downward, partially closing the foramen of Winslow The arrangement was almost as though the gall-bladder were inside a case of tissue The gall-bladder was not adherent to it and when this tissue was removed the peritoneal covering of the gall-bladder was intact" That there was no inflammation of the peritoneum was obvious when the gall-bladder was removed by dissecting its serosa

In two cases the usual attachment was present, running from the lesser omentum along the gall-bladder from cystic duct to fundus But then it was reflected posteriorly to the liver and abdominal wall, running across the duodenum and attaching to the hepatic flexure of the colon There seemed to be in these two cases two distinct layers of tissue, anterior and posterior, 4 to 5 mm apart, along the attachment to the gall-bladder

DIAGNOSTIC INVESTIGATION

The question as to whether congenital peritoneal attachments to the gall-bladder, duodenum and colon produce definite symptoms is difficult to settle It is important that efforts be made in this direction to throw more light on obscure symptomatology in the right upper quadrant of the abdomen, and to avoid unnecessary surgical interference, yet to be able to advise operation when indicated No definite symptom picture presents itself It may be that this very indefiniteness of the symptoms, such as vague discomfort in the right upper quadrant, anorexia or nausea, bloating, "sour stomach," or occasional sharp twinges of pain unrelated to meals, or perhaps increased following meals, are indications of anatomical disadvantages which prevent normal function

Homans³ who has made a careful study of symptomatology in 11 cases of "congenital transduodenal bands" has grouped symptoms under the headings of "intermittency," "food relief," "vomiting" and "bleeding" In his 11 cases, five had intermissions, some discomfort being more or less steadily present Six of the cases showed a definite food relief, but in others taking of food excited discomfort Vomiting was present in six of the 11 cases In none was there a history of hematemesis

In Homans' cases gastric analysis was of no value, some showing high and some showing low acidity

Roentgen-rays in three of nine cases of Homans which were studied showed duodenal defects, two, dilatations of the upper duodenum, one, hour-glass stomach. In one, hyperperistalsis was present, and in another, an atonic stomach.

Homans' cases were diagnosed as everything else than "transduodenal bands," the question of this diagnosis being brought up in only two of them. The most common confusions were duodenal ulcer and chronic cholecystitis. Three of Homans' cases were neurotic.

Meyers and Bloom believe that for diagnosis combined examination of the gall-bladder and the gastrointestinal tract is of no advantage, and hold that fluoroscopy is not practical on account of failure of visualization of the gall-bladder. They attribute significance to a "shifting deformity" of "Duval." "Duval deformity is differentiated from ulcer deformity in that the latter is constant in any one segment of the cap, whereas the former is shifting. Duval's deformity is differentiated from irritable cap in that with the former the cap is filled but the deformity occupies a varying segment of the cap and is still irregular after atropine." The impression of Meyers and Bloom is that no clinical entity can be built up from the symptoms in these cases and that periduodenal adhesions of this type are not significant clinically.

In the study of the symptomatology in my series, seven of the cases had to be ruled out on account of the presence of gall-stones, leaving 11 for study.

In two of the 11 cases the duodenum was deranged somewhat, in one of these the first part was pulled up by a short strand running to the liver, in the other there was a slight constriction at the second part. Both of these cases had more or less discomfort in the epigastrium and right upper quadrant after meals, with nausea and vomiting. Both were subject to migraine. One of the two was relieved considerably by cholecystectomy and section of the adhesions, but the other was practically unrelieved. They were followed three and five years.

In three of the cases where the gall-bladder was greatly constricted by abnormal sheets of peritoneum running across it, there was discomfort and irregular pain in the right upper quadrant associated with more or less nausea and vomiting, the pain being worse after meals. Following removal of the gall-bladder and congenital adhesions in these cases, symptomatic relief was obtained after an average period of one month. This has lasted for two years in two of the cases. The other patient could not be located for follow-up.

In the two cases where a loose veil covered the gall-bladder with a mesentery, relief for three and five years was obtained after removal of the vesicle.

With four cases in which the abnormal attachments were of lesser extent, and there were symptoms of gas, indigestion, feeling of fullness with epigastric discomfort after meals, removal of the gall-bladder and adhesions

gave relief in one for three years. One, who had been subject to migraine was unrelieved after three years, two who were neurotic were unrelieved after several months.

From the above records it will be seen that relief appeared to follow operation in those cases where the gall-bladder was restricted in its motion by the congenital adhesions or where the motion was abnormally free through a mesentery. The possibility with the hypermobile vesicle is that kinking of the cystic duct interfered with emptying. In one of the two cases with mesentery a transverse constriction of the gall-bladder was shown by the Graham test, although emptying was only slightly delayed, but in the other the gall-bladder was exceedingly large and emptied abnormally slowly.

Although Meyers and Bloom do not believe that *fluoroscopy* is of value it seems that this means to aid the diagnosis should not be lightly given up. The combined examination of the gall-bladder and stomach, duodenum and colon has been suggested several times⁴ and some studies have been carried out.⁵ If the "double-oral" method of cholecystography is used^{6,7} the gall-bladder in most cases can be visualized under the fluoroscope. If the shadow presents irregularities on the roentgenogram, such as apparent pulling of the fundus toward the mid-line, and if there is lack of mobility under the fluoroscope, adhesions are suspected. If under combined examination the gall-bladder, duodenum and hepatic flexure of the colon can not be separated, or are distorted, adhesions are probable. However, with a thick or tense abdominal wall manipulation of the viscera may be so difficult that nothing can be learned in this way. If the shadow of the gall-bladder hangs low or has an unusual alignment, and is hypermobile under the fluoroscope, it may have a mesentery as well as other peritoneal attachments. However, in the 12 cases with congenital adhesions in which stones were absent the diagnosis of "perivesicular" adhesions was made in only two cases. But this was worth attaining and is encouraging to further effort.

THE QUESTION OF TREATMENT

Rational treatment of these congenital right upper quadrant adhesions would depend upon definite diagnosis. If there were only moderate symptoms and a few abnormalities, like "shifting irregularity of the duodenal cap"² or "hypo-mobility" or "hyper-mobility"⁵ of the gall-bladder, medical treatment should certainly be tried first. It appears that a considerable number of these patients are neurotic. The relation here may be that neurotic individuals magnify slight symptoms produced by interference with motility of these organs in their normal physiological activities, or there may be functional disturbances elsewhere such as "irritable colon." These congenital adhesions might in many cases adjust themselves by stretching without an operation. Then, too, it must be remembered when contemplating operation that the postoperative adhesions might be more restrictive than

the congenital On the other hand if the patient has severe symptoms such as inability to hold food on the stomach to a dangerous degree, together with signs of irregularity or torsion of the duodenum or gall-bladder, operation is advisable

In the case where the previous diagnosis has not been made and congenital adhesions are found at operation, the question arises as to what to do. Constricting bands should certainly be relieved. It seems to me that the gall-bladder should be removed also. It is not a necessary organ and in all probability the dire results attributed to its loss have been exaggerated. If for good reason a surgeon exposed my gall-bladder I would thank him to remove it even though it appeared normal, provided of course, it were done with little trauma to abdominal viscera and without damage to the liver. During an operation for the removal of gall-bladder and congenital adhesions it must be kept in mind to leave as little raw surface as possible. In some cases it might be advisable to remove the gall-bladder and then only to relieve restricting bands, allowing a considerable amount of the peritoneal tissue to remain to prevent postoperative adhesions which might occur on surfaces from which it had been removed.

SUMMARY AND CONCLUSIONS

Congenital peritoneal adhesions to the gall-bladder are much more common than is ordinarily realized since they are found in about one-fourth of the population.

That many of these adhesions, or bands, do not produce symptoms is probable, but that some of them do is almost certain.

The symptom picture is hazy. It consists chiefly of vague right upper abdominal discomfort or pain—stabbing or dragging, intermittent or more or less constant—usually worse after meals, and often accompanied by nausea or vomiting. Neurotic symptoms may be prominent.

Preoperative diagnosis is difficult. It depends upon the above symptom picture, the elimination of other causes of right upper quadrant pain, under combined roentgenoscopy, lessened or increased mobility of the gall-bladder in relation to other viscera—perhaps tenderness.

Treatment should be first medical, with a view to reducing the alimentary load for a more or less crippled digestive system, second, psychological.

Surgery should be reserved for those cases where the roentgen-ray, including fluoroscopy, shows abnormalities, where other measures fail, and where pain and/or nausea and vomiting are severe.

Operative treatment consists in removal of the gall-bladder and section of constrictive bands or sheets of peritoneal tissue. Care must be taken to prevent secondary adhesions, or these may become more troublesome than the primary.

SAMUEL JONES GEE AND HIS FRIENDS *

By SIR HUMPHRY ROLLESTON, Bt, G C V O, K C B

PERHAPS the best way I can join in a tribute to Joseph Hersey Pratt—the clinical physician—is to offer a sketch of another clinical physician, at St Bartholomew's Hospital, with some sidelights on contemporary medical London when I was a student there half a century ago. The names of great physicians have often been linked by their admirers with recently recognized forms of disease, and also with favourite prescriptions—the least of their achievements. Samuel Jones Gee is an example of this eponymous association. Fifty years ago what is now known as posterior basal meningitis or, as Still showed in 1898, chronic meningococcal meningitis of infants was colloquially known in London as “Gee and Barlow's disease” after their account in 1878 of cervical opisthotonos in infants which in his aphorisms Gee later summarized as follows “not a tuberculous affection, it is due to a chronic meningitis of the medulla. It may, however, occur as a symptom in tuberculous affections of this region.” In 1899 Sir Thomas Barlow (1845–) and David Bridge Lees (1846–1915) gave an expanded account of the condition under the title of “posterior basic (occlusive) meningitis, acquired hydrocephalus.” These three writers were colleagues at the Hospital for Sick Children, Great Ormond Street, W C.

In 1888 Gee published an article of four pages “On the Coeliac Affection” beginning “There is a kind of chronic indigestion which is met with in persons of all ages yet is specially apt to affect children between one and five years old.” At the time it attracted very little attention perhaps because, like most of his original papers, it appeared in the *St Bartholomew's Hospital Reports* and not in the medical periodicals with their much wider circulation. In 1903 W B Cheadle (1836–1910), his colleague at the Hospital for Sick Children, gave an account of cases under the name of “acholia” and ascribed them to “inhibition of the liver”, Sir Byrom Bramwell (1847–1931) of Edinburgh in several papers between 1901 and 1915 described the condition as pancreatic infantilism, C A Herter (1865–1910) of New York “rediscovered” the disease in 1908 and started metabolic investigation of what he termed infantilism due to intestinal infection, Heubner (1843–1926) in the following year followed on the same lines, and the disease was sometimes called Gee-Herter and Herter-Heubner disease. The eponym “Gee's disease” appeared in 1926 in *The Manual of the International List of Causes of Death, as Adapted for Use in England and Wales Scotland and Northern Ireland* by the Registrar General, this tabular list contained a number of terms used by practitioners in signing death certi-

* Received for publication May 24, 1937

cates, and thus differs from *The Nomenclature of Diseases, Drawn up by a Joint Committee Appointed by the Royal College of Physicians of London* (1931) which gives very few synonyms and does not include "Gee's disease" The comprehensive article on this disease by Izod Bennett, Hunter, and Vaughan in 1932 was entitled "Idiopathic Steatorrhoea (Gee's Disease), A Nutritional Disturbance Associated with Tetany, Osteomalacia, and Anaemia" Since 1926 Thaysen of Copenhagen has written 10 papers arguing that the coeliac affection, non-tropical sprue, and tropical sprue should be grouped together under one designation "idiopathic steatorrhoea," and Mogensen of Copenhagen in 1937 suggested the eponym "Gee-Thaysen's disease" for those three conditions Henry Moore and his Dublin colleagues recommended that the coeliac disease of children should be called the "Gee-Herter disease," that idiopathic steatorrhoea of adults and adolescents of non-tropical countries should be known as the "Gee-Thaysen disease, and that the name sprue for the tropical disease should be retained" Years before his paper on the coeliac affection Gee's name became familiar in connection with a linctus composed of equal parts of compound tincture of opium, syrup of tolu, and oxymel of squill It was said that this prescription was not his, but that of a lady bountiful of a village, who had thus cured the obstinate cough of one of his hospital patients It became widely popular and in Smithfield, at the doors of the hospital which so freely supplied it to out-patients, "linctus tarts" were on sale It is interesting to recall his philosophical indifference to posthumous fame as merely meaning "the number of times after death the letters composing the man's name were put together in one order" (Legg)

Samuel Jones Gee was born on September 14, 1839, in London where his father, William Gee, was in business but was much interested in literature and frequented the British Museum His mother Lydia Sutton (1797-1888) was, like many mothers of great men, a remarkable woman His parents were somewhat puritanical Gee, the only one of their four offspring to survive infancy, was a delicate boy and never robust When eight years old he went to a private school in Enfield, a few miles from London, and from 1852 to 1854 he attended University College School Three years later he matriculated at the University of London, and as a medical student of University College Hospital came under the influence of Sir William Jenner (1815-98), whose example may in some degree have accounted for Gee's successful dogmatic teaching at the bedside In 1861 at the final examination for the degree of bachelor of medicine at the University of London he was bracketed with C Hilton Fagge (1838-83) for the gold medal and the University scholarship in medicine, in 1865 he proceeded to the M D degree and became a member, being elected five years later a fellow, of the Royal College of Physicians of London In the meanwhile he had become a member of the Royal College of Surgeons in 1863, and been appointed resident house surgeon to Richard Quain (1800-87) at University College Hospital in December 1862, earlier in that year he had been resident

house surgeon at the Hospital for Sick Children, Great Ormond Street. This hospital, the first solely for children in London, was founded in 1852 on the site of the mansion of that medical Maecenas, Richard Mead (1673–1754), largely as the result of the exertions of Charles West (1816–98), an

Samuel Gee

almost exact contemporary of Sir William Jenner, from 1848 to 1860 West lectured at St Bartholomew's Hospital Medical School on Midwifery, with which at that time diseases of children usually were nominally combined. It was not until 1904 that a special department for diseases of children was

established at St Bartholomew's Hospital, and was then placed under the care of Sir A. E. Garrod (1857-1936) and Dr H. Morley Fletcher, physicians to the Hospital and also on the staff of the Hospital for Sick Children and the East London (now Princess Elizabeth of York) Hospital for Children respectively. In Gee's time and for some years after, almost all the members of the staff of the Hospital for Sick Children were also attached to general Hospitals. Gee was appointed assistant physician in May 1865, physician in February 1875, and consulting physician in March 1885 to the Hospital for Sick Children. Like Thomas Addison and Hilton Fagge, particularly as regards dermatology, he was anxious to avoid the reputation of a specialist in any branch of medicine, and removed from the *Medical Directory* his title of consulting physician to the Hospital for Sick Children.

That Gee was house surgeon at University College Hospital and at the Hospital for Sick Children might now suggest that he inclined more to surgery than to internal medicine. But it is perhaps not generally realized that the post of house physician is more modern, at any rate in name, than that of house surgeon. At the Hospital for Sick Children the separate post of house physician was first established in December 1879. During the first half or more of the last century the work now done by house physicians was at most hospitals part of the duties of a resident medical officer, known as the apothecary, a title then in use for general practitioners. Thus at St Bartholomew's Hospital, London, Frederick Wood (1820-1906) was apothecary from 1847 to 1867 and performed the work later carried out by 14 qualified medical men, namely 10 house physicians, two junior assistant physicians, and two casualty physicians. In December 1867 four house physicians were created, and within a quarter of a century increased to ten. At Guy's Hospital the Stockers, father and son, were apothecaries, and the first resident house physician was appointed in 1868, a non-resident junior house physician being added in the following year, a house surgeon had been appointed in 1856. At the Radcliffe Infirmary, Oxford, there was a resident house-surgeon-apothecary until 1860 when a house physician was appointed, the last house-surgeon-apothecary but one there holding office for 12 years. At University College Hospital the name house physician at any rate was in use many years earlier, as is shown by the following information courteously supplied by the Secretary.

From its opening in 1834 the Hospital had an apothecary and a house surgeon. On December 7, 1841 the Medical Committee recommended that, as the duties of house-physician have always been performed by the apothecary, the titles as well as the duties of these offices be united, and after 1845 "house physician" often occurs in the Minutes. In 1851 on the recommendation of the Medical Committee the title apothecary was changed to resident medical officer, and in May 1880 that of "physician's assistant" to that of house physician.

In 1868 Gee was elected assistant physician to St Bartholomew's Hospital. It was then quite exceptional for the larger teaching hospitals in London to go outside their own school in order to fill vacancies on the permanent staff of the hospital. Indeed 20 years later a score of young would-be physicians were waiting about in the hope of becoming one of the eight on

the medical side of the staff During this period of probation the aspirants held minor teaching posts, such as demonstrators, in the medical school, or in connection with the hospital, such as medical registrars, on a salary so nominal as to be quite insufficient to keep body and soul together The competition was extremely severe and exacting, for it was not customary for the future consultants to engage in ordinary general or family practice, scholarships and grants for scientific research were then rarely available, and men without private means had to take pupils or undertake literary or other work to scrape together a living and to keep up appearances It was then and for years after a common complaint that many able men could not afford to become consultants The waiting time might be exceptionally tedious, especially when as very occasionally happened, several resignations and deaths occurred unexpectedly within a short time, and as a result the successors in office being comparatively young enjoyed an unusually long tenure of office, while their juniors had therefore to face a correspondingly increased period of probation At St Bartholomew's Hospital in the 'sixties of the last century the mortality among physicians was very high

William Baly (1814-61) in whose memory there is a gold medal for distinction in physiology at the Royal College of Physicians of London, was killed in a railway accident near Wimbledon, W S Kirkes (1823-64), distinguished for his work on embolism, the now forgotten hypothesis that chorea is due to miliary embolism in the corpora striata, and author of a textbook on physiology subsequently edited for many years by W D Halliburton (1861-1931), died from double pneumonia and pericarditis, a combination much more frequent then than now, Sir George Burrows (1801-81), afterwards president (1871-76) of the Royal College of Physicians of London, resigned in 1864, Henry Jeaffreson (1810-66) succumbed to typhus fever caught from a fatal case in a medical student under his care, G N Edwards (1830-68) died of renal disease, Robert Martin (1827-91) resigned in 1868 on account of a nervous breakdown when engaged to be married, this was a tragedy, for he soon recovered completely and returned to professional practice the next year in London, but a career of the brightest promise was irreparably wrecked, for "in London to step aside for a time is to be left behind" He was a charming white-haired gentleman with old-fashioned courtly manners, who often came to the post-mortem room or, as his generation called it, the dead house, and was an expert in the facial diagnosis of the cause of death He died of pneumonia, of which he had previously had an exceptional number of attacks, in 1869 F J Farre (1804-86) automatically ceased to be an active physician to the hospital on attaining the age-limit of 65 years

The way was thus opened for those waiting at St Bartholomew's Hospital, such as James Andrew (1829-97), Reginald Southey (1835-99), Sir William Church (1837-1928), and also for fresh blood, besides Gee, there were elected Sir Dyce Duckworth (1840-1928) in 1869 and Sir Lauder Brunton (1844-1916) in 1875, both Edinburgh graduates Wickham Legg (1843-1921), like Gee, a pupil of Sir W Jenner to whom, soon after Gee's election to St Bartholomew's Hospital, Sir James Paget said "Can't you send us another Gee?", was appointed to succeed Gee there as demonstrator of morbid anatomy in 1874, and as lecturer in that subject and assistant physician in 1878 He had qualified in 1867 and about this time was tutor to Prince Leopold (1853-84), the fourth and youngest son of Queen Victoria, this appointment was probably due to Sir William Jenner who from 1861 was the influential medical adviser of Her Majesty Prince Leopold was the subject of haemophilia on which Legg subsequently (1872) wrote

a treatise In 1883 he was selected by the president (Jenner) to deliver at the Royal College of Physicians of London the Bradshaw lecture founded in 1875 in memory of Dr W W Bradshaw of Oxford He chose "Cardiac Aneurysm" as his subject, and it may be noted that in 1889 Norman Moore (1847-1922) gave this lecture on "The Distribution and Duration of New Growths," and that Gee in 1892 followed in these footsteps of his juniors by lecturing on "The Signs of Acute Peritoneal Diseases" Legg's most considerable medical book was on "The Bile, Jaundice and Bilious Diseases" (1880) In 1887 he retired from St Bartholomew's Hospital and medicine to devote himself to liturgical subjects and bringing out numerous volumes for the Henry Bradshaw Society for editing rare liturgical texts, being Chairman of its Council from 1895 to 1915 Henry Bradshaw (1827-89), University Librarian, (1867-89) at Cambridge, and much interested in mediaeval liturgies inspired Moore, when a turbulent undergraduate at St Catherine's, with an interest in palaeography Gee, Legg, and Norman Moore who contributed 454 lives, mainly of medical men and Irish Saints to the first 63 volumes of the *Dictionary of National Biography* and others to its two supplements, formed a small group of colleagues, resembling the scholar-physicians in the time of Linacre (1460-1524), the founder and first president of the Royal College of Physicians of London Other like-minded contemporaries were W A Greenhill (1814-94), J F Payne (1840-910), and James Finlayson (1840-1906) of Glasgow, of these Norman Moore, the youngest and not the most profound, was probably the most successful in popularizing the history of medicine

At St Bartholomew's Hospital Gee was, for a short time in 1870, in charge of the skin department, established in 1867 This was in accordance with the rule then in force there that the assistant physicians and assistant surgeons should take charge of the special departments, and was in reality a compromising expression of the widespread dislike then felt by the leaders of the profession against specialism, a survival of the dictum that "a specialist is half a quack," ascribed to Sir Benjamin Brodie (1783-1862) who was president of the Royal Society, the Royal College of Surgeons of England, and the General Medical Council Gee found a more congenial occupation as demonstrator of morbid anatomy (1870-74), and lecturer on pathology from 1874 to 1878 when he became physician to the hospital and joint lecturer on medicine In obedience to the age limit of 65 years he became consulting physician in 1904

In 1901 he was appointed honorary physician to the Prince of Wales, afterwards King George V It has been suggested that his inability to yield to the weaknesses and foibles of mankind may have influenced the distribution of public honours as far as he was concerned, but probably, like Gallo, he "cared for none of these things" Indeed according to tradition, when asked by a most influential personage if he would like to be made a baronet, he replied that he would prefer a fur coat

With his clear and logical mind and after a most careful clinical examination of the patient Gee arrived at his diagnosis, which were very seldom wide of the mark, by an orderly process of exclusion and not by intuition. Osler spoke of him as combining the spirit of Hippocrates with the method of Sydenham. He was one of the best clinical teachers of his time in London, and his hospital rounds, made in the early afternoon, as is the custom in London, on three days in the week were always crowded, he naturally concentrated attention on the new cases, his opinion on nervous diseases being much quoted. Competition to be one of his clinical clerks for three months was keen, and to be his house physician, then resident for a year, W. H. R. Rivers (1864–1922) being the last under this arrangement, was a prize indeed. His house physicians, probably unconsciously, often adopted some of his peculiarities, such as turning back the lowest inch of their coat sleeves before examining a patient, this was a protection against parasitic invasion, and long before the time of white linen coats. The *Medical Notes* (1921) dedicated “to the Memory of My Teacher Samuel Gee” by Sir Thomas (now Lord) Horder, inevitably recall the collection of “Clinical Aphorisms from Dr. Gee’s Wards (1895–96)” which he published in 1897. In the early ‘eighties of the last century clinical medicine received comparatively little help from laboratory methods, clinical pathology being introduced at St. Bartholomew’s Hospital in the next decade, mainly by A. A. Kanthack (1863–98) the first whole-time teacher of pathology in the London medical schools. But I saw Gee sit down in one of his wards to stain sputum for tubercle bacilli soon after Koch described the method in 1882. As his colleague and friend Sir Thomas Barlow wrote, he was one of “the group of great Victorian physicians who held firmly the inseparable link between morbid anatomy and clinical medicine.”

At the Royal College of Physicians of London Gee was much in request, he held various offices and gave the following lectures. In 1871 the Goulstonian lectures on “The Heat of the Body”, this lectureship founded in 1632 by Theodore Goulston, M.D., F.R.C.P. is given to “one of the four youngest doctors of the College,” and it was further directed that a dead body should if possible be provided, a suggestion long ignored, the Lunleian lectures in 1899 on “The Causes and Forms of Bronchitis and the Nature of Pulmonary Emphysema and Asthma”, these lectures were endowed in 1581 by Richard Caldwell (1513–84), president of the College in 1570, and John, Baron Lumley (? 1534–1609), and was originally called in the annals of the College the Chirurgical Lectures, and the Bradshaw lecture which, as mentioned above, is of comparatively modern origin.

The Harveian Oration—the most honorable and perhaps the most difficult to discharge—Gee declined, perhaps more than once. It was founded in 1656 by William Harvey with a number of directions, some of which long ago fell into abeyance, for example, it was last delivered in Latin more than 70 years ago, and the complete commemoration by name of all the benefactors of the College is never attempted now. The reason suggested for

Gee's refusal was that being doubtful about the value of experiment in the natural sciences he felt that he could not obey Harvey's direction to exhort the fellows and members "to search and study out the secrets of nature by way of experiment" At the present day this attitude seems very strange, but Gee lived much in the past and preferred the old to modern ways It should, however, be mentioned that when Augustus Matthiessen (1831-70), lecturer on chemistry at St Bartholomew's Hospital Medical School, and C R A Wright discovered apomorphine in 1869 they handed it over for physiological investigation to Gee, who not only tried it on animals but was the first human being to be submitted to its action with the result that his initial scepticism about it being "a most powerful emetic and contrastimulant" was, as he fully admitted later, decisively demolished

Gee's personality was complex and therefore impressed people in different lights, he was thought by some to be shy and reserved, by others to be fastidious, he certainly was not a good "mixer" or of the "hail fellow well met" fraternity An unfavourable first impression was experienced by two of his life-long colleagues and friends

Francis Harris (1829-85) was elected assistant physician to the Hospital for Sick Children, Great Ormond Street, in 1859 and, in 1861 to St Bartholomew's Hospital, becoming full physician in 1868, he was thus Gee's senior colleague, the two men were very different, Harris being a Cambridge graduate of independent means who rather avoided private practice and was much devoted to field sports He had heard much about Gee, but without being attracted to him On one occasion when in poor health, he was advised by his friend Thomas Smith (1833-1909) to go away and get someone to take his out-patients, "Yes," said Harris, "but if there is one person I will not put on duty it is that beast Gee" He, however, was persuaded to do so, and eventually he and Gee became the greatest friends In his appreciative memoir Gee described a curious incident in connection with Harris's only published work—his thesis for the M D degree on "The Nature of the Substance Found in Amyloid Degeneration of the Various Organs of the Human Body" (1860) Not being accustomed to write for the press, Harris made little use of stops and in letters substituted dashes, in his thesis he followed his usual style, but when faced with the proofs was horrified by the numerous dashes which the printers had conscientiously copied

Howard Marsh (1839-1915), surgeon to St Bartholomew's Hospital and the Hospital for Sick Children, professor of surgery (1903-15) and Master (1907-15) of Downing College, Cambridge, described after Gee's death, the very frigid reception he received at their first meeting when he arrived, confessedly a day late, to succeed Gee as house surgeon at the Hospital for Sick Children, where later he and Sir Thomas Smith were Gee's colleagues and were instrumental in securing his election to the assistant-physiciancy at St Bartholomew's Hospital Marsh also mentioned Gee's outspoken criticism of men, how with his "eyes glowing with indignation and intense conviction" he would declare "the man is a scoundrel"

From Wickham Legg's *Recollections of Samuel Gee*, published in 1915, the following may be quoted, the first two *obiter dicta* having a somewhat Johnsonian flavour, "Sir, I have forgotten more anatomy than you ever knew", "Yes, Mill was an able fellow, but Bam was a dunderheaded Scotchman", his dismissal of the *Handbook of Therapeutics* (1869) by his contemporary Sydney Ringer (1835-1910) as "a book of little dodges", of the sudden death of Andrew Marvell the younger (1621-78) he said that it was not due to poison, but that he "was only murdered by his doctor who refused to give him the bark for a tertian ague" Many stories about him were current at St Bartholomew's Hospital, some apocryphal and even inherited from John Radcliffe (1658-1714) He was opposed to speculation, often quoting *hypotheses non fingo*, was profoundly critical and sceptical, and frequently changed his expressed opinion

He was prone to be pessimistic, thus in 1886 in a letter to Legg he sounded a despondent note "the struggle for life is so hard that those in the medical profession who are able to care for anything but making money are quickly becoming very few The learned physician is almost extinct And I am sorry for it, because the rank which the profession takes in the world depends chiefly upon the physicians" During the intervening 50 years the distribution of the relative spheres of influence has been much modified Of the modern Universities founded in the nineteenth century in England, including his own, that of London, he had a poor opinion When he had reached the three score years and ten of the psalmist he looked back without any satisfaction, care of his own health became something of a tyrant, and he concluded that life was but a sorry thing Describing himself as an "Old Whig" he had a contempt for politicians, did not read their speeches, and thought badly of this country's future

Wickham Legg who saw much of him heard him laugh heartily once only, Gee, however, had humour though generally dry and often so subtle that it escaped detection by the ordinary individual But there are exceptions to most rules, and Norman Moore, when laid up in Norfolk with an attack regarded as malarial, received from him the following lines

"I want to know, Moore, if you mean
To write a treatise on the spleen,
And if we find it does not plague you
To follow up with one on ague"

He hardly ever went to the theatre, painting, architecture, and music did not appeal to him in the least Norman Moore shared this lack of feeling for music, and could recognize one tune only, that of "God save the King," because every one then stood up Gee loved the birds and flowers of the country Like his teacher, Sir William Jenner, he strongly opposed the admission of women to the medical profession He was essentially a lonely soul, especially after the death of his wife and one of his two daughters Even as a younger man he preferred his own fireside to the

meetings of medical societies, at which his voice was little heard. But at the premier medical society in London, the Royal Medical and Chirurgical (expanded in 1907 into the Royal Society of Medicine), he sat on many committees and was honorary librarian (1887-99), being succeeded by Norman Moore. He certainly was not one of "the three Gs," three slightly junior contemporaries, so-called in the late seventies of the last century from their constant activities at medical societies in London, they were Sir W. R. Gowers, (1845-1915), Sir James Goodhart (1845-1916) and W. S. Greenfield (1846-1919), afterwards professor of pathology (1881-1912) at Edinburgh.

Extremely learned, Gee had read very widely from Hippocrates onwards and, though always pleased to discover that what was put forward as a new observation, had been anticipated by the Greeks he kept abreast of the modern German and French works on medicine. His favourite medical writers were Hippocrates, Sydenham and Heberden. His carefully trained memory seemed to retain all he read. His range of general literature was also extensive, especially of philosophy, he was attracted by the stoics, particularly Marcus Aurelius and Epictetus, and by the Cambridge Platonists, in 1872 he translated into English verse the hymn of Cleanthes (B. C. 300). Poetry, especially Wordsworth, appealed to him, and he was said to have known the whole of the "Prelude" and much of Pope's poems by heart, other favourite authors were Milton, George Herbert, Pascal, Montaigne, and Walter Scott. Matthew Arnold he spoke of as "the poet of despair." He was more in sympathy with the writers of the seventeenth and eighteenth centuries than with those of subsequent years. After his death it was said that he might have been a professor of English literature and equally well have occupied a chair of philosophy. With such encyclopaedic knowledge it is hardly surprising that he had a supreme contempt for any pretence of learning and hated a display of extensive reading. From the paucity of references in his published papers it would seem probable that he considered long lists of references as evidence of the author's vanity.

As a writer Gee began early and his concise style, which gave the maximum information in the fewest words possible, characterized his writing from the start, "thrift in words" being one of his mottoes. Sir John Russell Reynolds (1828-96), physician to University College Hospital enlisted with great success among the eminent contributors to his well-known *System of Medicine* in five volumes (1866-79) two young men from those under his eye at the hospital, Gee before he was thirty wrote in the first two volumes on chicken-pox, scarlet fever, and tuberculous meningitis, the last especially being an admirable study of the natural history of the disease. The other was Sir William R. Gowers who supplied classical articles on diseases of the blood-forming organs, being probably thus led to invent his haemocytometer (1877) and haemoglobinometer (1878), before his name became so predominantly associated with neurology—the branch of medicine which then especially attracted able young physicians.

Gee took much trouble in the choice of words, and preferred an English to any foreign word, thus "all of one mind" was better than "unanimous" and "hereafter" than "for the future." Legg thought that he took special interest in a man with dysentery who, when asked what he complained of, answered "Sir, the bloody flux." It was not unnatural that when asked in the closing years of the last century to write the article on pleurisy in Allbutt's *System of Medicine*, the successor of Russell Reynolds' *System*, he stipulated that no editorial changes should be made in what he had written. Later in conversation he expressed his dislike of "what is called getting up the literature" and this no doubt weighed with him in selecting T. J. (now Lord) Horder to revise the article for the second edition in 1909. But this expression of opinion was a few years before his death, and he had practised as well as preached the precept never to write on a subject until the literature had been thoroughly mastered. He contributed 46 papers to the *St. Bartholomew's Hospital Reports*, but wrote two books only. The first *Auscultation Percussion Together with Other Methods of Physical Examination of the Chest* appeared in 1870 and reached a fifth edition in 1907, the fourth edition being dedicated to the memory of Laennec. The text was largely composed as he walked to the hospital, when he would turn into a side street to jot down a sentence just constructed. From its logical form it has been compared to Euclid's propositions, and in 1901 he remarked "this book taught me more in the writing than it will teach anyone else in the reading." The other book *Medical Lectures and Aphorisms* appeared in 1902 and was dedicated to the memory of Sydenham. It passed into a fourth edition in 1915 when Wickham Legg added to it his "Recollections of Samuel Gee" with a signed and pleasing photograph. It contained 272 aphorisms of which 258 had been collected by J. T. Horder in 1897 who was his house physician and follower, they condensed a vast amount of practical medicine. The following may be quoted.

- No 59 "Pneumonia is not a local, but a universal disease, and the brunt of it may fall upon any part—lungs, endocardium membranes of the brain, intestines, kidneys"
- No 81 "Pericarditis is not so common now as formerly, a fact which must be attributed to the use of sodium salicylate in the treatment of rheumatic fever. Endocarditis, however, seems to be as common as ever"
- No 231 "Tache cérébrale is a sign of little or no value"
- No 257 "There is often a remarkable latency about diseases of old people. Phthisis particularly is often overlooked because of its supposed improbability"
- No 258 "As a rule people do not die 'of old age.' There is usually failure of a particular organ, and not of all together. Still, it is sometimes very difficult to say exactly from what an old person does die"

Gee's important paper on "The Clinical Enlargement of the Spleen in Hereditary Syphilis and Some Other Diseases in Children" was read on March 26, 1867 before the Royal Medical and Chirurgical Society. He showed that in the early stages of congenital syphilis the spleen was palpably enlarged in half the cases and reached a considerable size in a quarter of the cases, the mortality in the second category was very high, and the degree of splenomegaly was therefore an index of the severity of the infection. The paper, however, was not considered to be worthy of publication in the Society's *Transactions*, this was not a unique mistake in the somewhat erratic decisions of the Society's referees, for the same judgment was passed on the paper on the open-air treatment of tuberculosis in 1862 read by Henry MacCormac (1800-86), and on several papers between 1857 and 1860 on the recently described Addison's disease, though not by Addison who much resented this ruling. As Gee's paper was never published in full there was some misconception about its contents, and accordingly Sir Thomas Barlow at the great debate on visceral syphilis at the old Pathological Society of London in 1875 loyally asserted the value of Gee's conclusions. At one time Gee drew up a plan for a history of medicine, and he published a paper on "Sects in Medicine" (1889) and on Abraham Cowley (1903), but unfortunately he soon gave up the larger project.

Gee married on December 7, 1875 Sarah, daughter of Emanuel Cooper, a member of the Society of Friends, whom in the formal, old-world manner of speech, which in his young days had suggested that he too was a Quaker, he described to one of his colleagues as being "quite adequate". His best man was Robert Bridges (1844-1930) who was his pupil at St Bartholomew's, a colleague as assistant physician at the Hospital for Sick Children and poet Laureate in 1913. In his *Carmen elegiacum de Nosocomio Sti Bartholomaei Londinensi* (1877), dedicated to Patrick Black (1813-79), whose house physician he had been, Bridges summarized, in Ovidian verse, the characteristics of the staff, containing references to Gee such as *Tute, Gei, mihi quam dulce et habuisse magistrum*.

Gee died suddenly in an anginal attack on August 3, 1911, when with his surviving daughter at Keswick on the English Lakes, a necropsy, for which he had left instructions with his lawyer, showed extensive atheromatous change in the aorta and aortic valves. He left an estate of £34,879, not a large sum for a successful consulting physician.

CASE REPORTS

ANEMIA AS THE CAUSE OF SEVERE CONGESTIVE HEART FAILURE REPORT OF A CASE

By ELMER C BARTELS, M D , F A C P , *Boston, Massachusetts*

THAT anemia can be the primary cause of organic heart disease is doubtful it can, however, give rise to quite abnormal subjective and clinical signs For such disturbances to arise it is necessary for the anemia to be severe It may be of the type characterized by a low level of the hemoglobin and a moderate reduction of the erythrocytes or of the type in which both factors are reduced Certain criteria are necessary before a diagnosis of heart disease attributable to anemia can be made, namely (1) presence of a marked anemia, and (2) disturbance of cardiac function

Herrick and Nuzum,¹ in 1918, first called attention to the association of pernicious anemia with angina pectoris They found four cases among 200 cases of angina pectoris Coombs,² in 1926, in a series of 36 cases of pernicious anemia found this combination in nine Cabot,³ in his book published in 1926 mentioned three cases of intense and typical angina and pernicious anemia without changes in the coronary arteries Herrick,⁴ in 1927, described three more instances, in two of which necropsy disclosed arteriosclerotic change of the coronary arteries He remarked on the rarity of the association

Willius and Giffin,⁵ in 1927, reported an incidence of 43 cases of angina in 1,560 cases of pernicious anemia These were cases in which the anemia was of long standing The angina had the same clinical features as the angina of coronary disease, but there were no changes detected in the heart and the electrocardiograms were normal

Reichel,⁶ in 1929, reported a series of 114 instances of pernicious anemia with angina pectoris present in three Gwyn,⁷ in 1932 in a consideration of angina pectoris and anemia stated his opinion that the coronary artery must have undergone some pathologic change to produce the syndrome The absence of angina pectoris in most cases of severe anemia was suggested as being attributable to the fact that the entire heart has degenerated and hence the ventricular balance is not upset Case reports on this subject by many authors 7, 8, 9 10, 11, 12, 13 14, 15, 16, 17, 18 have appeared

Gunewardene,¹⁹ of the Indian Medical Service reported in 1933 on the frequency of heart failure in ankylostomiasis In these cases severe anemia and marked cardiac dilatation accompanied by signs of congestive failure were often present On treatment and cure of the infection the heart returned to normal size and the murmurs disappeared Smith,²⁰ in 1933, made an electrocardiographic study of the heart in 15 cases of severe anemia The blood pressure in seven of these was normal In none were characteristic alterations of any sort found, in any phase of the electrocardiographic deflections

* Received for publication December 1, 1936

From the Medical Department of Lahey Clinic, Boston, Massachusetts

Pickering and Wayne,²¹ in 1933, reported on 25 cases of anemia. Eight of these patients complained of substernal pain with or without exertion. In six cases pain did not continue after the anemia had been cured. In two it persisted. The occurrence was not restricted to any particular type of anemia. The tolerance to exercise seemed to improve with the elevation of hemoglobin, but pain could still be produced with greater exertion. In four severely anemic patients the same exercise no longer produced pain or tightness in the thorax when the level of hemoglobin in the blood was 50 per cent.

Elliott,²² in 1934, reported a case of anemia, caused by repeated severe uncontrollable epistaxis, with severe angina in the presence of healthy coronary arteries and aorta. The heart at necropsy weighed about 601 gm. There was no clinical evidence of hypertension. The cardiac hypertrophy was explained on the basis of the chronic anemia. The stress of exertion together with the acute loss of blood was felt to be sufficient to precipitate myocardial ischemia with resultant angina pectoris. The electrocardiogram showed alterations in the R-T segment.

Ball²³ reported a case in which changes in the heart were demonstrated by roentgenology in the presence of severe anemia. This was a case of severe menorrhagia from fibroids in which there were definite symptoms of myocardial failure with enlargement of the heart and murmurs. After surgical removal of the uterus the murmurs disappeared and the roentgenogram revealed reduction in the size of the heart on return of the blood to normal.

In severe anemia certain changes in function of the cardiovascular system do occur. In the early stage the pulse rate increases and then an elevation of the blood pressure appears with a relative decrease in the pulse pressure. This changes later into a true cardiac and vascular insufficiency. A recent report by Grunberg²⁴ based on 111 cases, 49 of which were cases of pernicious anemia and 62 of secondary anemia, demonstrated this change. Changes in the size of the heart were also noted with enlargement to the right and left as the anemia progressed.

Changes in the cardiovascular mechanism during anemia are entirely the result of an attempt at compensation. Fahr and Ronzone²⁵ studied the circulatory compensation for deficient oxygen capacity of the blood in severe anemia and found that there was an increase in the minute volume output of the blood in addition to a lowered viscosity of blood and that the skin capillaries were contracted to half normal size in an effort to increase the blood flow through the vital organs. One can conceive of this attempted compensation going to the point where partial or complete failure of the heart ensues.

CASE REPORT

A white man, a printer aged 76 years, was admitted to the hospital June 12, 1935, complaining of severe dyspnea on exertion and orthopnea of three months' duration. A family history of diabetes and of numerous gastrointestinal diseases was obtained. He had been married for 30 years and had had no children. His past history was essentially negative except for a history of indigestion for 15 years associated with vomiting of blood on two occasions and black stools on one occasion. All three of these episodes were 15, 13 and 11 years before admission respectively. For years he had taken soda to relieve his epigastric pain which usually came on one hour after eating. He had never had distress at night. For the last year he had taken soda

almost every day because of epigastric pain. He had been watching his stools carefully but had not noticed gross blood or tarry stools.

Three months before admission the patient had begun to notice dyspnea on walking up a slight incline to his office. He had no associated pain in the thorax. The dyspnea seemed to get worse each day and although he did not stop walking, when he arrived at his office he was gasping for breath and it was necessary for him to sit down and rest. He consulted his physician five weeks before admission and was told he was jaundiced and had a severe anemia. A potent preparation of liver was prescribed which the patient continued to take for five weeks. No improvement resulted. His dyspnea progressed so that it appeared on the slightest exertion. It was impossible for him to lie down and sleep, so he sat in a chair most of the time. Prior to onset of his illness he had lost about 10 pounds in weight, but in the last three months his weight had increased gradually and swelling of the entire body had occurred.

Examination on admission to the hospital revealed an extremely pale old man with moderate swelling of the face. His weight was 206 pounds. The blood pressure taken while he was at rest in bed was 154 mm of mercury systolic and 74 diastolic. The pulse rate was 100 beats per minute and was regular. There was a slight icteric tinge to the sclerae and a suggestion of jaundice of the skin. His voice was quite hoarse and there was an irritating, non-productive cough. The pupils which were small and irregular reacted sluggishly to light. The teeth were all absent. The thyroid gland could not be palpated. The thorax and arms were edematous so that pressure produced deep pitting. No gross pleural fluid could be detected but coarse rales were heard through the lower portion of both lungs. The heart was percussed slightly to the left of the midsternal line. Its tones were distant, regular and no murmurs were present. The abdomen contained a large quantity of free fluid. The abdominal wall showed marked pitting edema. Although the liver was not palpable there was definite tenderness in the right upper quadrant of the abdomen. The scrotum and peris were moderately edematous and the legs revealed marked pitting edema. The rectal examination was essentially negative.

The laboratory studies revealed the number of erythrocytes to be 1,800,000 per cubic millimeter of blood. The value for hemoglobin was 35 per cent. The total leukocyte and the differential counts gave normal results. The urine had a specific gravity of 1.020, was alkaline in reaction and contained a trace of albumin. The phenolsulphonphthalein test was 45 per cent in two hours. The value for non-protein nitrogen was 28 mg and for urea nitrogen, 17.7 mg. The value for serum protein was 6.4 gm, for cholesterol, 96 mg, for blood sugar, 120 mg, for serum bilirubin 2.6 mg and for blood chloride, 531 mg per 100 cc. The Hinton reaction of the blood was negative. The venous pressure was 22 cm. The stools were found to contain blood. Analysis of gastric content revealed a total acid of 54 and a free acid of 36.

Because of the marked edema and since the kidney function was apparently normal, measures to induce diuresis were instituted. The patient was given ammonium chloride, the intake of fluid was restricted and 14 cc of salyrgan were administered in divided doses in 15 days. Marked diuresis resulted, the patient losing 60 pounds. His general condition improved as the edema lessened and when his weight reached 146 pounds, he said that he felt fine and the edema and orthopnea had disappeared.

Investigation was instituted immediately to determine the source of the blood in the stools which had persisted in spite of a meat-free diet. The patient's condition was so improved that roentgenologic studies of the stomach were carried out and these revealed a persistent niche at the junction of the first and second portions of the duodenum with a rather marked narrowing at this point.

A diagnosis of duodenal ulcer with chronic bleeding and severe secondary anemia was made and dietary treatment and administration of large doses of iron were begun. At the time the patient was dismissed from the hospital, or 25 days after admission,

the erythrocyte count was 3,080,000 and the value for hemoglobin 44 per cent. One and a half months later the erythrocyte count was 5,260,000 and the value for hemoglobin, 94 per cent. At that time also the patient's weight was 151 pounds. He felt perfectly well and was back at work. He did not have the slightest evidence of dyspnea on walking, slept flat in bed and had no evidence of gastric distress. At present, one and a half years after his dismissal from the hospital, he is in good health and is working every day.

COMMENT

On admission to the hospital this patient presented all the features of severe cardiac decompensation. His condition responded to administration of diuretics in the usual way for primary heart disease with failure. On alleviation of the secondary anemia the patient was able to return to his activities and his cardiac symptoms disappeared. This patient had the usual amount of arteriosclerosis for patients of his age, but there was no associated hypertensive or valvular disease and no history to suggest myocardial infarction. That the anemia was the precipitating factor in the decompensation of the heart seems certain and is further borne out by the course of the disease. No digitalis has been used by the patient since he was dismissed from the hospital.

THE DIAGNOSIS OF SOLITARY LIVER ABSCESS BY MEANS OF THOROTRAST HEPATOSPLENOGRAPHY

Report of a Case¹

By WALLACE M YATER, M D, F A C P, and JOHN R CAVANAGH, M D,
Washington, D C

DURING the past five and one-half years we have employed Thorotrast for the purpose of demonstrating lesions of the liver and spleen in several hundred patients. This method of roentgenographic diagnosis was developed mainly by Oka¹ and Radt² about 1929. It consists in the intravenous injection of 50 to 75 c c (for adults) of a stabilized colloidal solution of thorium dioxide manufactured under the name of Thorotrast,[†] following which roentgenograms of the abdomen are made. The thorium dioxide is rapidly engulfed by the reticulo-endothelial cells of the body, and because it is radiopaque it is possible to demonstrate the size, shape and structure of the liver and spleen, which contain these cells in greatest concentration. Cirrhosis of the liver and neoplasms are particularly well shown. Although thorium dioxide is somewhat radio-active and remains for years in the body we have not observed serious immediate or remote ill effects from its use. Yater, Otell and Hussey³ have reviewed their first 200 patients examined over a period of five years and have failed to note harmful results. They describe the technic and the information that can be derived from the study of hepatosplenograms. Their first patient has recently returned for a checkup five and one-half years after the injection of 60 c c of Thorotrast. Although the roentgenogram shows shadows of the liver and spleen almost as dense as originally, she is in the best of health, in spite of the fact that the diagnosis of chronic lymphatic leukemia was made by competent clinicians six years ago and roentgen-ray treatment employed therefor.

* Received for publication February 15, 1937

From the Georgetown University School of Medicine

† Manufactured by the Heyden Chemical Company

The opportunity to demonstrate liver abscess by means of hepatosplenography does not present itself often and we feel justified in reporting a case. Reeves and Apple⁴ used Thorotrast for this purpose successfully in a case of amebiasis reported in 1933.

CASE REPORT

Clinical Course A white barber, aged 38 years, entered Georgetown University Hospital on July 24, 1936. Prior to May 10, 1936 he had been well since childhood, when he had had measles, mumps, pertussis and chicken-pox. On May 10, 1936 he had developed a severe attack of pain in the right upper quadrant of the abdomen which radiated to the right axilla. After a few days he had returned to work in spite of continued but less severe pain. Six weeks before admission the pain became worse and fever was first noted. The pain was practically continuous from then on and the fever persisted. The pain was described as sharp and stabbing, starting about 8 cm. to the right of the umbilicus and radiating to the right costal margin. There was also a dull, constant ache in the right lumbar region. For three weeks before admission he had vomited at intervals. A loss of 40 pounds had resulted. On the day before admission a chill had occurred. There had been no bowel disturbance.

The patient appeared to be seriously ill. There was no jaundice. The temperature was 101° F, the pulse rate 100, and the respiratory rate 22 per minute. There were numerous carious teeth, the tongue was dry, and the tonsils were hypertrophied and slightly inflamed. The heart and lungs appeared normal and the diaphragm moved normally bilaterally. The abdomen was flat and symmetrical. On deep palpation there was marked tenderness over the lower portion of the right lobe of the liver, which could be felt about 6 cm. below the right costal margin and seemed to have a rounded edge. The hemoglobin was 56 per cent, the red blood cells numbered 3,180,000 and the white blood cells 26,050 per cu. mm. of blood, with 82 per cent polymorphonuclear neutrophils. Other laboratory studies including urinalysis, van den Bergh reaction, bromsulphthalein test of liver function, Wassermann and Kahn tests of the blood, and repeated stool examinations were normal or negative.

During the first two and a half weeks in the hospital the temperature was very irregular and ranged from 98° F to 103° F, being elevated practically every day. The condition became progressively worse, and a bronchitis aggravated the pain. Abscess of the liver was suspected early and it was decided to make hepatosplenograms. On July 27, 28 and 29, by intravenous administration 25 c.c. of Thorotrast were given, and on July 30 a roentgen-ray film was made of the abdomen. The appearance of the film, interpreted in conjunction with the clinical course, was definitely that of a large solitary abscess of the right lobe of the liver. Further roentgen-ray films were made at intervals after operation.

On August 10, 1936, Dr. William C. Gwynn opened the abdomen and found the right lobe of the liver to be enlarged with a rounded edge, and a rounded mass about the size of a medium-sized orange projected from its under surface. The omentum and parietal peritoneum were sutured to the anterior surface and edge of the liver adjacent to the mass, and a gauze packing was placed in the pocket thus formed. Two days later the incision was re-opened and an aspirating trocar and cannula inserted through the isolated area of liver into the mass. About 150 c.c. of thick reddish brown pus were aspirated, after which a large rubber drainage tube was placed in the abscess cavity and the area again packed with gauze. Pus continued to drain in gradually diminishing amount. Amebae or other organisms were not found in the pus, but a course of injections of emetine hydrochloride was given. On the tenth day after operation the tube was removed and the wound slowly healed. The irregular fever continued for three weeks after operation, when the temperature be-

came normal The patient was discharged as cured on the fortieth day after operation

On March 10, 1937 the patient was re-admitted to the hospital He had remained well until one week before, when he became feverish and weak During this week he had had several chills, and tenderness had developed in the upper right quadrant of the abdomen Examination revealed slight enlargement of the liver, tenderness near McBurney's point, and dry rales in both lungs The temperature on admission was 104.6° F, the pulse rate was 120 and the respiratory rate 20 per minute

FIG 1 Pre-operative hepatosplenogram, showing enlarged right lobe of liver with large area of lessened density in lower portion, the demarcation not being clear cut

The blood pressure was 85 systolic and 58 diastolic The urinalysis was normal The hemoglobin was 57 per cent, erythrocytes numbered 3,600,000 and leukocytes 14,800 per cubic mm of blood, with 84 per cent polymorphonuclear neutrophils A roentgenogram of the chest showed an area of opacity in the middle of the right lung field, which was thought to indicate interlobar pleurisy A barium study of the colon showed a constant area of narrowing of the transverse colon, which was thought to be due to an adhesion from the old operative scar A hepatosplenogram was made, this did not throw any light on the present illness Several stool examinations were negative for amebae A blood culture was negative The Craig test for amebiasis gave questionable results The temperature became normal after

ten days The hemoglobin and erythrocyte count gradually rose to normal, while the leukocyte count rose to 17,000 The course of injections of emetine hydrochloride was repeated but not until after the temperature had been normal for several days The patient left the hospital after four weeks, apparently well The exact cause of the liver abscess or of the second illness was not determined

Description of Hepatosplenograms The first films showed the right lobe of the liver to be moderately enlarged downward (figure 1) There was normal hepatic opacity in the upper three-fifths of the liver shadow, but the lower rounded portion

FIG 2 Hepatosplenogram made two weeks after operation for solitary abscess, showing abscess cavity about half its original size

was relatively non-opaque The upper rounded edge of this non-opaque area was not sharp but was rather "fuzzy," characteristic of an abscess without a well formed wall The left lobe of the liver was not enlarged, and the spleen was of normal size Films made two days before operation were quite similar A hepatosplenogram made two weeks after operation showed the abscess cavity to be about half its original size (figure 2) One month after operation the right lobe of the liver was practically normal in size, and the abscess cavity was about one-fourth its original size Two months after operation there was a small mottled area of somewhat less opacity than the main mass of liver in the lower edge of the right lobe (figure 3) Apparently the

abscess cavity had contracted and become filled in with reparative tissue. The reproductions of these hepatosplenograms show far less detail than the films themselves. The hepatosplenogram made in March 1937 showed no appreciable change from the previous one.

FIG 3 Hepatosplenogram made two months after operation, showing healed area in lower portion of right lobe of liver

COMMENT

The conditions that must be differentiated from solitary abscess of the liver in hepatosplenograms are neoplasm and cyst. Neoplasms, especially metastatic carcinoma, are usually multiple. They appear as round areas of lessened opacity with a clear cut edge and often a halo of condensed liver tissue about them. Solitary tumors of the liver are rare but have a sharper outline than abscess. The same is true of echinococcus cyst. While the outline of an abscess is irregularly circular, it is not sharp but "fuzzy" and blends with the adjacent liver parenchyma. It has a homogeneous appearance in its central portion as does a neoplasm, since pus does not contain reticulo-endothelial cells, at least

none capable of removing foreign bodies from the blood stream. The roentgen appearance should be pathognomonic when the clinical history is considered in conjunction with it. Hepatosplenography is merely a laboratory method of diagnosis and should be employed by the clinician and roentgenologist with the clinical picture in mind, although often a correct diagnosis of hepatic lesions can be made from a study of the films alone.

EDITORIAL

BENIGN LYMPHOCYTIC CHORIO-MENINGITIS

In 1925 Wallgren¹ collected and described under the term "acute aseptic meningitis" a group of cases of meningitis which began abruptly and ran a benign course, which showed a lymphocytosis in the cerebrospinal fluid from which no bacteria could be isolated by smear or culture, and in which the recognized diseases capable of causing this symptom complex could be excluded. Since this publication many similar cases have been reported both in America and in Europe, and the condition is evidently not uncommon.

The clinical picture has varied considerably. The onset may be preceded by symptoms of an acute respiratory infection, or of "influenza." More often it is abrupt, with severe headache, fever, drowsiness, photophobia, vomiting and stiffness of the neck. In the mildest cases headache may be the principal complaint, and after an illness of two or three days, the symptoms may subside and permanent recovery ensue. More often the illness lasts from one to several weeks, but recovery eventually occurs without sequelae. In other cases the symptoms are more severe. There may be delirium, dizziness, marked drowsiness or excitability, restlessness and apprehension. Anorexia and constipation are usually marked. Transient pareses or even paralyzes, usually of the cranial nerves, have been described, but there are no outspoken paralyzes, as in poliomyelitis. There may be respiratory disturbances. Kernig's sign is often positive. Reflex disturbances are common, either exaggeration, diminution, or inequality of the deep reflexes. There is often slight swelling of the optic discs. Viets and Warren² have reported one case that died after convulsive seizures.

The cerebrospinal fluid has been found under increased pressure. The fluid is colorless, clear or slightly turbid. The cells are always increased, usually from 200 to 2000 or more above the norm, and over 90 per cent are lymphocytes. The lymphocytosis persists for several weeks in convalescence. In the severer cases the globulin is increased and the sugar and chlorides somewhat diminished. Cultures are sterile and tubercle bacilli are not found. The colloidal gold test may show a meningitis type of curve.

In the case of Viets and Warren there was a marked lymphocytic infiltration of the meninges, which extended deep into the brain substance along the vessels. There were areas of degeneration and gliosis, and in places the nerve cells showed inclusion bodies.

Recent investigations have shown that in a limited number of these cases the disease is due to a filtrable virus. This was first isolated by Armstrong

² VIETS, H. R., and WARREN, S. Acute lymphocytic meningitis, Jr. *Am. Med. Assoc.*, 1937, cviii, 357.

and Lillie in 1933³ from the brain of a monkey, the sixth in an inoculation series, the first of which had been inoculated with the brain emulsion of a human case supposedly of encephalitis of the St Louis type. In 1935 Scott and Rivers⁴ isolated a virus, later found to be identical, from the cerebrospinal fluid of two human cases of the disease, by intracerebral inoculation into mice. Traub⁵ also obtained the same virus from a colony of mice which had been naturally or accidentally infected.

Intracerebral inoculation into mice of infected cerebrospinal fluid or virus suspensions causes an encephalitis in most of the animals. The symptoms appear after five to six days and consist chiefly of tremors, clonic convulsions, and tonic spasm of the hind legs. The virus is present in the brain, but also in the blood and other organs. At necropsy the animals show a lymphocytic infiltration of the meninges and choroid plexus and a virus bronchopneumonia. Those which survive are immune to reinoculation.

Monkeys can be infected by intracerebral inoculation, and the disease may spread spontaneously among them.

Guinea pigs are highly susceptible, both to intracerebral and subcutaneous inoculation. After seven or eight days they show fever, which may be the only symptom, loss of weight and signs of general illness. The distribution of the virus and the lesions are like those in mice. Guinea pigs which survive become immune, and their serum will neutralize the virus and prevent the infection of other mice or guinea pigs. The serum of human cases has also acquired protective power, but this develops only after six to ten weeks.

Because of the characteristic pathological lesion the disease caused by the virus is commonly called benign (or acute) lymphocytic chorio-meningitis. Clinically it must be differentiated especially from tuberculous meningitis, from poliomyelitis, from epidemic encephalitis, and from the encephalitis that occasionally occurs as a sequel of various other virus diseases such as mumps and vaccinia. A positive diagnosis can be made by demonstrating the virus in the spinal fluid at the onset of the disease by inoculation into mice or guinea pigs. It may also be made by demonstrating protective power in the serum late in convalescence. One of these procedures is necessary since many cases showing this clinical picture fail to show the virus in the cerebrospinal fluid and do not develop protective power, and presumably are due to some other etiological agent.

The wide distribution of the disease is shown by the fact that Armstrong demonstrated protective power in the serum of six individuals from widely separated sections of this country. Furthermore Findlay, Alcock and

⁵ TRAUB, E. Filterable virus recovered from white mice, *Science*, 1935, **81**, 298.

Stern⁶ recovered the same virus from cases of human infection and from mice in England. It is not certain whether man or the mouse constitutes the primary reservoir of infection, but it is believed to be man. Further study will probably show that the disease is more common than the number of reported cases would suggest. Recognition is important, particularly from the standpoint of prognosis, although the occurrence of severe and even fatal cases must be recognized.

REVIEWS

Body Water By JOHN P. PETERS, M.D. viii plus 405 pages, 16 × 23 cm Charles C. Thomas, Springfield, Illinois 1935 Price, \$4.00

In spite of the extensive literature covered in "Body Water," this monograph can hardly be regarded as a general review of the water balance. No mention is made, for example, of the total water content of the body or of the distribution of fluid in various organs. Dr. Peters has quite frankly limited himself to those phases of this broad subject in which he and his co-workers have been particularly interested. The book might best be described as a critical analysis of some of the basic problems pertaining to the exchange of fluid in man. The author has clearly made a determined effort to see just how far the known facts can be explained by physico-chemical laws, and failing to find a satisfactory explanation on this basis, he stretches neither facts nor laws for the sake of reaching definite conclusions. Unfortunately, the result of this searching attitude seems to be a book in which the reader finds it difficult to extricate the facts from the discussions.

"Body Water" begins with a detailed discussion of the "chemical forces involved in exchange of fluid and solutes." One-third of the book is then devoted to the internal fluid exchange, following which there are two chapters on "Water of oxidation and the losses of water and solute through the skin and respiratory passages" and "Alimentary exchanges." The remaining third of the book is concerned entirely with the kidney.

Dr. Peters does not hesitate to deal harshly with existing theories. For example, he launches a vigorous campaign against the views of Drinker and Field on the mechanism of lymph formation. Contrary to the opinion of these authors, he also contends that the amount of protein in tissue fluid is small as compared to that present in lymph. In reviewing the chemical data on cerebrospinal fluid, Dr. Peters finds inadequate support for the hypothesis that this fluid is a simple ultrafiltrate of serum. Recent evidence discrediting the once popular theory of "bound water" is also cited.

The first chapter on osmotic pressure is in certain respects misleading. Osmotic pressure is simply an expression of the difference in diffusion pressure of the solvent in different parts of the system, and not due to a tendency of the solutes to expand as Dr. Peters seems to imply by the following statement: "The solutes which exert pressure in a solution are restrained by the boundaries of the fluid system in which they may be dissolved. Changes of the volume of the system cannot be effected by direct expansion of the solutes as they are in gases but only by the addition of solvents."

The emphasis here is upon the solute whereas in reality the only part that the solute plays in the phenomenon is that of "diluting" the solvent.

The discursive nature of many sections of "Body Water" makes it rather difficult reading for those chiefly interested in general information. This characteristic of the book, however, is perhaps not due so much to the author's method of presentation as to the complexities of a subject in which many of the fundamental facts are still lacking. A more didactic treatment would in many instances be unjustified and serve only to give the erroneous impression that general agreement existed on questions which are far from settled.

M I G

A Mind Restored By ELSA KRAUCH 242 pages, 14.5 × 21 cm G. P. Putnam's Sons, New York 1937 Price, \$2.50

This book, bearing an introduction by William Seabrook, author of "Asylum" and of various travel tales, is another account of the experiences of a man suffering mental illness which required hospitalization. The tale describes the development of

a common type of depression which gradually progressed to the point that this man was unable to care for his own affairs, lost his business, went through a "rest home," a small, private sanatorium of the type which is unhappily not uncommon and finally had himself voluntarily admitted to a state hospital. After a period of months in the state hospital he made a social recovery and in the course of the next two years feels that he has recovered completely. Certainly he is again apparently a useful, self-supporting member of society and one who has learned a great deal from the experiences he lived through. Most of the book is devoted to his experiences in and reactions to the state hospital.

During the past several years there have been a number of such tales intended for general reading, designed to allay some of the fears which exist about mental disease and about conditions which are popularly supposed to exist in our institutions. A great many physicians find these books of the better type useful in demonstrating to their patients that other people suffer the same experiences and in giving the patient's family some allegedly inside information. This is one of the best of such books. It gives a fairly satisfactory, objective account of life in a state hospital. It is not Pollyannish, neither is it bitter. It will probably be a good book for selected depressive patients, particularly middle-aged groups and for families to read. It is one of the few books of this type which can be recommended for this purpose.

H M M

Allergic Diseases Their Diagnosis and Treatment By RAY M. BALYEA, M.A., M.D., F.A.C.P., Assisted by RALPH BOWEN, B.A., M.D., F.A.C.P. Fourth Edition. xv plus 516 pages. F. A. Davis Company, Philadelphia. 1936. Price, \$6.00.

In the preface to the first edition of this work, the author states that it is written primarily to teach patients "concerning the possible causes of their trouble so that they may acquaint themselves more thoroughly with the animal and plant life with which they are surrounded, as products from one or both of them frequently cause their attacks." In the preface to the present edition, he revises this, stating that it has not been written for those doing special work in allergy, but for the general practitioner.

In attempting to estimate the usefulness of the volume, its content seems to be too voluminous and detailed for a patients' manual, and, at least in part, too elementary to be very useful to the physician. Thus, there seems to be no very good reason for the inclusion in a patients' handbook, of detailed directions for the intratracheal administration of iodized oil, nor should the patient be familiar with the technic of collection, staining, and examination of nasal secretions. Though an effort has been made to keep the terminology simple enough to be understood by the intelligent layman, technical expressions, without adequate explanation, are frequently used. The physician who expects much help in the treatment of patients, will probably be disappointed in the complete lack of detail as to methods of hyposensitization by hypodermic administration of atopens. The omission of a discussion of constitutional treatment reactions, and the author's statement that they do not occur (p. 225) are surprising.

On the whole, however, this volume is easy to read, interesting, and, at times, valuable. The section on botany is very helpful, well illustrated, and contains a number of pollen maps. Directions to patients for the elimination of offending substances should be useful.

I N C

Diseases of the Nose and Throat By C J IMPERATORI and H J BURMAN 16 X 23 cm, 723 pages J B Lippincott Company, Philadelphia 1935

This new work on the diseases of the nose and throat is one that can be used by both senior medical students and practitioners alike. The volume consists of 52 chapters and 480 illustrations, covering 723 pages. It begins by giving a detailed description of office equipment and arrangement. This is followed by an outline of history taking and methods of examining the patient.

A review of the anatomy and physiology is presented, followed by discussion of the various affections of the nose and throat. One is accustomed to having etiology and pathology presented early in the discussion of a disease, but the authors have preferred to present first the symptoms, then the diagnosis, treatment (medical and surgical), pathology, complications, etiology, and prognosis in the order named.

The descriptions of operative technic are very clear and well illustrated.

A rather lengthy description of the diseases that can be diagnosed and treated with the aid of the bronchoscope and esophagoscope is included. A chapter is devoted to physical therapy methods in diseases of the nose and throat. Allergic manifestations in the upper respiratory tract are adequately discussed.

The style is very simple, it is one of the easiest of books to read. The type is large and the topics are arranged in somewhat the form of an outline. There are not a lot of unnecessary details to wade through, but at the same time nothing essential is omitted.

T R O'R

Reports on Chronic Rheumatic Diseases By THE BRITISH COMMITTEE ON CHRONIC RHEUMATIC DISEASES, Edited by C W BUCKLEY, M D, F R C P 159 pages, 17 X 25 cm Number one 1936 The Macmillan Co, New York Price, \$4 00

The stated purpose of this report by the British Committee on Chronic Rheumatic Diseases is to stimulate interest and research in the causes and treatment of rheumatic conditions and to develop more coordination of information and activities not only in Great Britain, but throughout the world.

The book is divided into three parts. The first includes a foreword, a description of the Committee organization, and a report of the Subcommittee on Nomenclature. A series of seven original articles on various phases and types of arthritis forms the second part, and four articles of review type constitute the third part. An extensive world-wide bibliography of articles written during 1936 completes the book, the arrangement of this section is by country, which gives one a better opportunity of comparing the activities of each nation.

The report of the Nomenclature Subcommittee is very interesting and is very detailed. It not only suggests a workable classification but explains its merits. The section on Clinical Criteria offers ample material for discussion and comparison of facts between the arthritis of known etiology and that of unknown. A careful and complete collection of all facts and features of each type is presented in apposing columns.

The original articles present material of much interest and value. The section called Critical Commentaries offers a review of the important international literature of the year and in general summarizes the feature articles from many countries and from different branches of medicine and surgery.

The report as a whole makes very interesting and instructive reading and tends to carry out its basic idea, namely to stimulate international coordination of thought and action in so important a disease. It may well be studied by student, practitioner and specialist.

Dr Carl H Gellenthien (Fellow), Valmora, N M, presented a lecture on "The Diagnosis and Differential Diagnosis of Pulmonary Tuberculosis" before the Diagnostic Clinic and Fifteenth Annual Assembly of Twin Lakes District Medical Society at Burns' Alhambra Pavilion, Twin Lakes, Rockwell City, on June 17

Dr B S Pollak (Fellow) Secaucus, N J, sailed on July 31 for Lisbon, Portugal, to attend the bi-annual Conference of the International Union Against Tuberculosis, which will be held at Lisbon September 5 to 9

Dr Edward E Cornwall (Fellow), Brooklyn, N Y, read a paper on "Diet and Longevity" before the American Therapeutic Society at its annual meeting held at Atlantic City, June 4

The following Fellows of the College were selected as speakers in connection with the tenth annual Graduate Fortnight, presented by the New York Academy of Medicine, from November 1 to 12

Dr George Baehr, New York, N Y, "The Pathology of Nephritis",
 Dr Robert F Loeb, New York, N Y, "Clinical Aspects of Nephritis",
 Dr Herman O Mosenthal, New York, N Y, "Clinical Aspects of Hypertension, Including Malignant Hypertension"

Dr Homer Davis (Fellow), Genoa, Nebr, has been elected President-Elect of the Nebraska State Medical Association

At the recent annual meeting of the North Carolina State Tuberculosis Association, held in Southern Pines, Dr Paul A Yoder (Fellow), Winston-Salem, N C, was elected President of the Association

Dr Roland A Davison (Fellow), Tucson, Ariz, has been appointed Medical Director of the Desert Sanatorium, succeeding Dr Louis B Baldwin (Fellow), Tucson, Ariz

Dr Alphonse McMahon (Fellow), St Louis, Mo, was elected President of the American Therapeutic Society at its annual meeting held in Atlantic City in June

Dr F M Pottenger (Fellow, Regent, and Past President) presided as President at the meeting of the Association for the Study of Internal Secretions, held at Chalfonte-Haddon Hall, Atlantic City, June 7 and 8, 1937 His presidential address was on the subject of "Early History of the Association for the Study of Internal Secretions" Dr Pottenger had previously served as President of the Association during the term 1935-1936, and was Secretary of the Association during the years 1917 to 1935

Dr Pottenger also gave an address on the evening of June 4 at the meeting of the American Therapeutic Society in Atlantic City His subject was "The Clinical Versus the Public Health Point of View in the Treatment of Tuberculosis"

Dr George W McCoy (Fellow), former director of the National Institute of Health, Washington, D C, has been assigned by the U S Public Health Service to make a study of leprosy in continental United States and the island possessions

Dr John E Gordon (Fellow), field director of the International Health Division of the Rockefeller Foundation, New York, has been appointed professor of preventive medicine and epidemiology at Harvard University Medical School

Dr Austen Fox Riggs (Fellow and Life member) received an honorary degree of Doctor of Science from Williams College, Williamstown, on June 21, 1937

Dr Edgar M Dunstan (Fellow) has resigned as Medical Director of Baylor Hospital to become Superintendent of the Dallas City County Hospital System

Dr Fred M Mevner (Fellow) Peoria, Illinois, represented the National Tuberculosis Association of the United States at the meeting of the British National Association for the Prevention of Tuberculosis at Bristol, England, July 1, 2, 3 He addressed the conference on "Nutrition and Environment in Open Air Schools" and also on "Dispensary Methods"

OBITUARIES

DR MUNFORD SMITH

Dr Munford Smith (Fellow) of Los Angeles, California died of cerebral thrombosis June 28, 1937 aboard the Motor Ship Canada bound for Panama. Dr Smith had left with Mrs Smith for the ocean trip as part of a convalescence from a recent period of ill health.

Dr Smith was born December 3, 1892, in Pittsburgh, Pa. He had his early education there and at Bucknell College. He received his medical degree from the University of Maryland in 1919. That same year he became associated with the Barlow Sanatorium which association he held at the time of his death. He was Medical Director of the Sanatorium for the past ten years. Dr Smith was active in many organizations. He was a member of the Los Angeles County, California State and American Medical Associations, the California Tuberculosis Association, a director of the National Tuberculosis Association and President of the American Sanatorium Association. He was an able and popular man, active and interested in his work with many friends both in and out of the profession who greatly miss him and his activities.

EGERTON L. CRISPIN, M.D., F.A.C.P.

DR C. L. SHERRILL

Dr Cote Long Sherrill (Fellow), of Statesville, North Carolina, the son of Walter and Anna Long Sherrill, was born September 4, 1887, in Texas. He received his academic education at Wake Forest College, N. C., and graduated in medicine at the North Carolina Medical College in Charlotte in 1914. He spent his internship at the Stetson Hospital, Philadelphia, and pursued post-graduate studies in several New York Hospitals, the Mayo Clinic, and various other clinics of the country.

Entering the U. S. Army in November, 1917, he was commissioned a captain, promoted to his majority in May, 1918, and sailed for France in August of that year. He was discharged July 19, 1919, as a lieutenant colonel, later entering the Medical Reserve Corps as a full colonel, which commission he held at the time of his death. He was very active in Legion affairs, was local Post Commander for one term, and held various executive offices with the state department of the Legion. He was elected National Commander of the Wildcat Division in 1936.

He was chief of the medical department of the H. F. Long Hospital, Statesville, N. C., at the time of his death, June 24, 1937, of coronary occlusion. His medical societies embraced his local and state medical societies, the American Medical Association, and he was made a Fellow of the American College of Physicians in 1931. For several years he had served as a member of the Postgraduate Committee of the N. C. State Medical Society,

and at the last meeting of this society he was also made Chairman of this Committee as well as Chairman of the Section on Medicine

In 1917 he married Miss Mary McLam, and leaves three living children in addition to his widow. He was a member of the Methodist Church, and was considered a leading spirit in the affairs of his community. His hobby was fishing. While not given to writing or publication, he was a faithful attendant of the medical societies to which he belonged, an earnest student of medicine, a hard worker, and a fine gentleman who will be missed by all who knew him.

C. H. COCKE, M.D., F.A.C.P.,
Governor for N. C.

DR. WILLIAM WALLACE BEHLOW

Dr. William Wallace Behlow (Fellow), Lieutenant Commander, Medical Corps, United States Navy, retired, died April 29, 1937, at the Palo Alto Hospital, Palo Alto, California.

Dr. Behlow was born in San Francisco April 8, 1886. He was a graduate of Leland Stanford University, receiving the degree of A.B. in 1907. In 1912 he received the degree of M.D. at Harvard University, following which he interned at the Boston City Hospital. Following his internship he returned to California where he practiced his specialty, internal medicine, and served on the Faculty of the Medical School of the University of California.

On the declaration of war in 1917, Dr. Behlow patriotically gave up his private practice of medicine and enrolled in the United States Naval Reserve in the provisional grade of Assistant Surgeon. He reported for active duty at the Navy Yard, Mare Island, California on May 26, 1917. Following this he took the professional examination for entrance into the Medical Corps of the Navy and he was commissioned an Assistant Surgeon in the regular service dating July 19, 1917. In April, 1918, Dr. Behlow reported on the destroyer *U. S. S. Taylor* for duty at sea, and in 1919 he was transferred to the battleship *U. S. S. Idaho* as junior medical officer with the present Surgeon General of the Navy. This was followed by duty at the Recruiting Station, Salt Lake City, Utah, and an assignment with the Second Base Force, U. S. Marines, San Diego, which was followed by a tour of duty with the Bureau of Medicine and Surgery in the Personnel section. His next assignment was to the hospital ship *U. S. S. Relief*. From this duty he went to the United States Naval Hospital, Brooklyn, New York, where he was later hospitalized and finally placed on the retired list. Following retirement he reestablished his residence in San Francisco, California.

Dr. Behlow was commissioned a Passed Assistant Surgeon with the rank of Lieutenant, U. S. Navy, on June 6, 1920. He was commissioned Surgeon with the rank of Lieutenant Commander, U. S. Navy, on June 4, 1925 and he was placed on the retired list on December 1, 1931.

Dr Behlow was a very high type of medical officer professionally and personally, and was regarded as an outstanding internist among his colleagues. He was noted particularly as a specialist on contagious diseases. He was unmarried.

P S ROSSITER, M D , F A C P ,
Governor for United States Navy

DR PETER JURJENS POTHUISJE

Dr Peter Jurjens Pothuisje (Fellow), of Denver, Colorado, died June 4, 1937

Dr Pothuisje was born in Holland on February 27, 1866 and was naturalized at Seattle, Washington, about 1887. He received his pre-medical training at DePauw University and his medical training at the University of Ohio, graduating in 1893. At various times he pursued postgraduate work in Chicago and New York City.

Dr Pothuisje was Consultant in Internal Medicine to St Joseph's Hospital since 1910, to St Luke's Hospital since 1922, to St Anthony Hospital since 1906, and to Beth Israel Hospital since 1923. He was on the active service of the Denver General Hospital. He was a member of the Medical Society of the City and County of Denver, the Colorado State Medical Society, and the American Medical Association, and had been a Fellow of the American College of Physicians since 1924. During the World War, he served with rank of First Lieutenant U S A.

Dr Pothuisje is survived by his wife, Lois Renette Tabor Pothuisje, and by two daughters, Lois, the wife of Dr Ivan W Philpott, of Denver, and Lucille, the wife of Mr Lawrence Stubbs, of Wichita, Kansas.

Dr Pothuisje was an able internist, devoting special attention to gastroenterology. He was a beloved family physician and those who knew him have suffered a great loss.

GERALD B WEBB, M D , F A C P ,
Governor for Colorado

DR VAUGHAN LE ROY SPRENKEL

Dr Vaughan Le Roy Sprenkel (Associate), Allentown, Pennsylvania, died June 18, 1937, at the Jefferson Hospital, Philadelphia, as a result of a cerebral accident terminating a chronic state of purpura hemorrhagica.

Vaughan Sprenkel was born in Perkasio, Pa, in 1906. He attended the Public Schools of Perkasio, York and Allentown and completed his pre-medical education at Muhlenberg College, Allentown. He graduated, with honors, from the Jefferson Medical College, Philadelphia, in 1931. Dr Sprenkel's internship was served at the Sacred Heart Hospital, Allentown, and in June 1932 he married and began his professional practice in Allentown.

Tragedy entered his life when his young bride died, in 1933, as the result of a complication after childbirth but, like the brave man he ever proved to be, Dr Sprenkel sublimated his grief and sorrow by attempting to help others

To write the obituary of a physician who lived but 31 years and whose professional life was, as a consequence of its brevity, very largely preparation for a future of work must give one pause

Those intimately associated with Vaughan Sprenkel are aware that from boyhood he was a practical idealist and, as he matured, he selected the profession of medicine as an agency of altruistic and unselfish service to others

After receiving his medical degree and completing his internship Dr Sprenkel planned and executed an admirable course of postgraduate instruction

His routine visits to Philadelphia hospitals kept him informed concerning the scientific work of a medical center and his enthusiasm, industry and earnestness brought him to the attention of those deeply interested in the progress and future of honorary scientific and medical associations

Dr Sprenkel became an Associate Fellow of the College in 1935. He was the youngest member of the International Association of Medical Museums and was, also, one of the youngest men to be selected for the honor of membership in the American Therapeutic Society. Dr Sprenkel's brief professional career was successful in the highest and best sense of that much abused term

He had learned in his student and interne days that the profession of Medicine must ever remain an Art, with a sound basis of Science and from the day he entered practice he was wisely far more interested in his patients than in the disease they were suffering from. Dr Sprenkel was admired and loved by those who knew him best and the medical profession and our College has suffered a serious loss in the too early passing of this talented young physician

E J BEARDSLEY, M D , F A C P ,
Governor for Eastern Pennsylvania

MINUTES OF THE BOARD OF GOVERNORS

St Louis, Mo

April 19, 1937

The first meeting of the Board of Governors of the American College of Physicians, held in connection with the Twenty-first Annual Session, St Louis, Mo, was called to order at 5 05 p m, April 19, 1937, at the Jefferson Hotel, with Dr Charles H Cocke, Chairman, presiding and the following Governors, or their representatives, present, and with Mr E R Loveland acting as secretary of the meeting Dr Fred W Wilkerson, Dr H P Mills (representing Dr W Warner Watkins), Dr Turner Z Cason, Dr Glenville Giddings, Dr James G Carr, Dr C W Dowden, Dr E H Drake (representing Dr Edwin W Gehring), Dr Henry M Thomas, Jr, Dr G W F Rembert, Dr Louis H Fligman, Dr R W Mendelson (representing Dr LeRoy S Peters), Dr J R Scott (representing Dr Walter W Palmer), Dr A B Brower, Dr T Homer Coffen, Dr Charles T Stone, Dr Louis Warfield (representing Dr Rock Sleyster), Dr James F Churchill, Dr G B Gilbert (representing Dr Gerald B Webb), Dr Wallace M Yater, Dr Samuel E Munson, Dr Robert M Moore, Dr Thomas Tallman Holt, Dr William B Breed, Dr Maurice C Howard (representing Dr Adolph Sachs), Dr Allen A Jones, Dr Leander A Riely, Dr E L Bortz (representing Dr E J G Beardsley), Dr Clement R Jones (representing Dr E Bosworth McCready), Dr J Owsley Manier, Dr Louis E Viko, Dr W E Ogden (representing Dr Jabez H Elhott), Dr Oliver C Melson, Dr Clarence K Canelo (representing Dr Ernest H Falconer), Dr Joseph E Knighton, Dr Henry R Carstens, Dr Edward L Tuohy, Dr A Comingo Griffith, Dr H W N Bennett (representing Dr Robert B Kerr), Dr Clarence L Andrews, Dr Charles H Cocke, Dr C F Gornly (representing Dr Alexander M Burgess), Dr Kenneth M Lynch, Dr J Morrison Hutcheson, Dr Charles E Watts, Dr Walter E Vest, Dr D Sclater Lewis, Dr Perceval S Rossiter, Dr Thomas Parran and Dr Edgar V Allen (Adviser to Dr E L Tuohy)

Chairman Cocke declared those attending the meeting as alternate Governors were automatically seated, if their credentials had been presented to the Executive Secretary, or to him

Abstracted Minutes of the preceding meetings of the Board of Governors at the 1936 Session were read, and, upon resolution, were approved

At this point, Chairman Cocke recognized the President of the American College of Physicians, Dr Ernest B Bradley, who addressed the Board He especially stressed the efficient aid the Governors had given to the College, and especially to the Committee on Credentials during the past year

Chairman Cocke then reported upon the deliberations of the Board of Regents at its earlier meeting He referred particularly to two amendments, one to the Constitution and one to the By-Laws, which had been considered by the Board of Regents at their December, 1936, meeting and subsequently published in the "Annals of Internal Medicine" These amendments related to limitations in the membership outside of Internal Medicine and to new standards of admission He said that after more mature thought and study, the judgment of the Board had been that the amendments should not be presented at the present time, on which there would be a further report at the General Business Meeting of the College

Chairman Cocke also referred to the matter of the Governors being the guests of the Regents during the past two or three years at the opening of the Annual Sessions, and expressed the hope that the Board of Governors might do something a little more concrete than just extend formal thanks

On motion by Dr Allen A Jones, seconded and unanimously carried, it was

RESOLVED, that the Board of Governors extend to the Board of Regents an invitation to Dinner at the opening of the 1938 Session

Secretary Loveland was called upon to present communications, whereupon he reported that he had received many letters from Governors who were unable to be present, several appointing others to act in their stead

Chairman Cocke read to the Governors the list of candidates for Associateship and Fellowship who had been elected by the Board of Regents on April 18, and reported that their names would be posted on the Bulletin Board, where every one could consult the list

Chairman Cocke then presented the list of Associates who were subject to being dropped for failure to qualify for Fellowship in the five-year period The list had been reported to all the Governors concerned by the Executive Secretary, but each Governor was now given an opportunity to make any supplementary report before definite action had been taken by the Board of Regents

Dr C W Dowden requested information as to how an Associate so dropped might later qualify for Fellowship The Executive Secretary reported that there had been but two cases that had come up as precedents In one case the Associate had not qualified for Fellowship because of serious illness He was later permitted to be proposed directly for Fellowship and not required to serve another five-year term as an Associate The other case also had some extenuating circumstances connected with it, with the result that the candidate was considered directly for Fellowship as a special case However, there must be adequate reason for such special consideration

Chairman Cocke then presented the list of members who were subject to being dropped for two years' delinquency This list also had been previously circulated among the Governors, so that every one was informed Every one on the delinquent list had been advised on many occasions of his delinquency, and the Executive Secretary now felt there was no further action that could be taken, other than to proceed with the provisions of the By-Laws Various members on the list were discussed, and no changes were made

Dr Cocke then reported upon the eighteen additions to Life Members since the last meeting, making a total of seventy-eight He also reported upon the acquisition of the new College Headquarters, describing its architecture, location, facilities, etc, and invited the members of the Board to visit the headquarters whenever they are in Philadelphia

Dr Wilkerson, Governor for Alabama, proposed that the meetings of the College be so arranged as not to conflict with the meetings of the Alabama State Medical Association There was general discussion of the time of the meetings, but it was pointed out that it is impossible to arrange the meetings of the College without some State society in some part of the country later selecting the same time Chairman Cocke, however, said that the program committee took every possible step to avoid conflicts

Dr E L Tuohy, Governor for Minnesota, inquired as to how much credit is given to the character of histories and autopsies presented by candidates Chairman Cocke replied that all histories and autopsies presented by candidates are examined by the Committee on Credentials to determine if they give evidence of careful preparation, proper history taking, proper laboratory studies, and correlation and discus-

sion of findings and diagnosis. He pointed out that the Committee on Credentials not infrequently returns histories which they feel have been delegated to secretaries or internes. Dr Cocke further pointed out that candidates are also judged from other standards, such as the presentation of publications, theses or proof of certification by one of the national certifying boards.

Dr Tuohy then recommended that the American College of Physicians should resort also to some sort of a report from the hospitals in which candidates are doing their work. This would act as an indirect means of inducing candidates to be more diligent and to more carefully observe the rules and regulations of the institutions. These sorts of inquiries, in addition to the presentation of histories, theses, etc., would give a further line-up on the character and qualifications of the candidates.

Chairman Cocke agreed to convey this suggestion to the Committee on Credentials, and suggested to Dr Tuohy that he also discuss the matter with the Chairman of this Committee.

In further discussion of the matter, it was pointed out that the superintendent of some hospitals is a nurse whereupon the suggestion was made that these inquiries should be sent to the Chief of Staff.

Dr Robert M Moore, Governor for Indiana, made a further suggestion that candidates who have recently changed from a large center to a small center should be given a period of time to become established before being considered for membership. The small city presents some obstacles to the continued restriction of practice to Internal Medicine, and some delay in accepting such candidates may afford a period of observation to determine whether they will be eligible in the new location.

Chairman Cocke then requested all members of the Board of Governors to join the Convocation procession on the evening of April 21.

Adjournment

Attest E R LOVELAND,
Executive Secretary

MINUTES OF THE BOARD OF GOVERNORS

St Louis, Mo

April 21, 1937

The second meeting of the Board of Governors of the American College of Physicians, held in connection with the Twenty-first Annual Session, St Louis, Mo, was called to order at 12 50 p m, April 21 1937, at the Jefferson Hotel, with Dr Charles H Cocke, Chairman, presiding, and Mr Loveland acting as secretary. The roll call disclosed the following Governors, or their representatives, present: Dr H P Mills (representing Dr W Warner Watkins), Dr Turner Z Cason, Dr Glenville Giddings, Dr James G Carr, Dr C W Dowden, Dr E H Drake (representing Dr Edwin W Gehring), Dr G W F Rembert, Dr Louis H Flugman, Dr R W Mendelson (representing Dr LeRoy S Peters), Dr A B Brower, Dr T Homer Coffen, Dr Charles T Stone, Dr Louis Warfield (representing Dr Rock Sleyster), Dr James F Churchill, Dr Wallace M Yater, Dr Samuel E Munson, Dr Robert M Moore, Dr Thomas Tallman Holt, Dr William B Breed, Dr Maurice C Howard (representing Dr Adolph Sachs), Dr Allen A Jones, Dr Leander A Riely, Dr E L Bortz (representing Dr E J G Beardsley), Dr J Owsley Manier, Dr Louis E Viko, Dr W E Ogden (representing Dr Jabez H Elliott), Dr Oliver C Melson, Dr Clarence K Canelo (representing Dr Ernest H Falconer), Dr Joseph E

Knighton, Dr Henry R Carstens, Dr E L Tuohy, Dr A Comingo Griffith, Dr Clarence L Andrews, Dr Charles H Cocke Dr C F Gornly (representing Dr Alexander M Burgess), Dr J Morrison Hutcheson, Dr Charles E Watts, Dr Walter E Vest and Dr D Slater Lewis

Chairman Cocke thanked the alternate Governors for attending the Session and the meetings of the Board

Upon motion by Dr C W Dowden, seconded by Dr A B Brower, and regularly carried, it was

RESOLVED, that the reading of the Minutes of the preceding meeting of the Board of Governors be dispensed with

Chairman Cocke reported on the preceding meetings of the Board of Regents, mentioning particularly the following items

(1) The Board of Regents has determined to appoint a Committee on Exhibits and Advertising to make a thorough survey, and to report back upon standards for raising the character and type of exhibits at the Annual Sessions and the type and character of advertising accepted in the ANNALS OF INTERNAL MEDICINE,

(2) The Board of Regents has appointed a Committee to formulate plans for a Revolving Fund to be available for Associates of the College to pursue postgraduate work to adequately qualify themselves for the examinations of the American Board of Internal Medicine,

(3) The Board of Regents has appointed a Committee on Postgraduate Education to organize courses of from two to four weeks either preceding or immediately following the Annual Sessions of the College these courses to be available to Fellows and Associates of the College at minimum cost These postgraduate courses will be organized in connection with the next Annual Session of the College They will cover every branch of Internal Medicine In view of the fact that the College always holds its Annual Sessions in large medical centers exceptional postgraduate facilities will be available,

(4) The Board of Regents has appointed a Consulting Committee to work with the Executive Secretary in connection with the publication of the 1937 Directory of the College, this Committee to have power in determining how Fellows and Associates shall be listed, and to designate what specialties and sub-specialties shall be recognized in the Directory

In the discussion that followed it appeared to be the consensus of opinion that the Board of Governors favor listing Fellows and Associates in the same section of the Directory, and not in separate sections as heretofore A suggestion was made that under the geographical index, the names of Fellows should be listed first and the names of Associates should be listed immediately thereunder

On motion by Dr C W Dowden seconded by Dr O C Melson, it was

RESOLVED, that the above recommendation be communicated to the Committee on the Directory and to the Board of Regents

On motion by Dr C W Dowden, seconded by Dr O C Melson, and regularly carried, it was

RESOLVED, that a transcript of the discussion by the Board of Governors be transmitted to the Consulting Committee on the Directory (Full discussion is recorded verbatim in the Executive Secretary's office)

There was a general discussion of the postgraduate courses to be offered by the College, it being pointed out that the courses are distinctly for members of the College, that the courses would be furnished at a very much lower cost than they are available elsewhere Dr Vest suggested that the courses should be made available also to candidates for membership

Upon motion by Dr Holt, seconded by Dr Dowden, it was

RESOLVED, that the Board of Governors recommend to the Board of Regents that the postgraduate courses extend over a period of not less than two weeks and possibly up to a period of a month

The Executive Secretary distributed mimeographed copies of the financial reports for the year 1936, and then proceeded to answer questions and explain various details related thereto

Chairman Cocke called for a discussion among the Board of Governors of the subject "allied specialties" as it now appears in the Constitution and By-Laws of the College

Dr Griffith moved and Dr Melson seconded the following motion

RESOLVED, that the Board of Governors recommend to the Board of Regents the retention in the Constitution and By-Laws of the words "and allied specialties"

The motion was opened for discussion, Dr Cocke explaining that "allied specialties" refer to pediatrics, neurology, psychiatry, pathology, tuberculosis, pharmacology, dermatology, bacteriology, roentgenology and public health. He explained further that the retention of these specialties within the scope of the College would continue to make available to the College the results of the investigations by men in these specialties

Dr Cason, Governor for Florida, expressed the opinion that the allied specialties should be eliminated. For example, he pointed out that the pediatricians have their own society and their own certifying board, the same being true in some of the other allied specialties, such as roentgenology. He felt that practitioners of the allied specialties would attend the meetings of the College less and less

Dr Breed, Governor for Massachusetts, expressed the opposite opinion, saying that he felt it would be suicidal for the College to restrict itself to the term Internal Medicine. The allied specialties should be retained within the By-Laws, and the gastroenterologists, dermatologists, etc., should be discouraged from setting up their own certifying boards

Dr Munson, Governor for southern Illinois, expressed the opinion that those engaged in the allied specialties who are interested in the College should be retained, and that programs of clinics should be provided to retain their interests

Dr Carr, Governor for northern Illinois, expressed the opinion that in keeping the pre-clinical men in the College, the College not only is showing respect for them, but will eventually obtain the help of men who are doing the most work along investigative lines. He said it would be a tragedy to eliminate from his part of Illinois those who are working continually and doing investigative work. The professors of physiology, bacteriology and pathology, and their associates in the medical schools of Chicago, are a decided asset to an institution like the College. They are called upon whenever a study of the fundamentals of medicine are desired. Such men had given him valuable help in the conduct of the Chicago program of the College

Dr Andrews, Governor for New Jersey, pointed out that whether the College membership is restricted to Internal Medicine or not, the program committee is free to invite surgeons, pathologists, or any others, to give papers and to participate in the clinics. He expressed the opinion that he favored the time when members of the College could say that the American College of Physicians is restricted to Internal Medicine

Dr Dowden, Governor for Kentucky, pointed out that the difficulty in the proposition under discussion had arisen in an effort to properly define the word "internist". In further discussion, he distinctly favored the retention of the "allied specialties" within the College. Many of those practicing allied specialties need a higher knowledge of Internal Medicine than many others who practice Internal Medicine exclusively

Chairman Cocke pointed out that certification by the American Board of Internal Medicine should not be construed as being synonymous with Fellowship in the American College of Physicians. Membership in the College may mean much more than mere certification, because other considerations would enter into the matter of Fellowship than mere certification.

After further discussion of the definition of membership in the American College of Physicians, the question was put to a vote and the resolution unanimously adopted.

PREVENT TETANUS

with NATIONAL TETANUS TOXOID

(Refined Alum Precipitated)

For producing an active immunity to tetanus in persons subjected to repeated wounds in the industries and in all branches of the military service Active immunization may last for years Cost is moderate Reactions and pain of injections are negligible Refined Tetanus Toxoid contains no serum and cannot cause serum reactions Tetanus Toxoid should be used for prophylaxis and never for treatment of tetanus! Tetanus Toxoid produces an active immunity against tetanus

Important In injuries give Tetanus Antitoxin for immediate protection if patient has not been previously immunized with Tetanus Toxoid

TREAT TETANUS with full doses of NATIONAL TETANUS ANTITOXIN

(Refined and Concentrated Globulin)

PREVENT SMALLPOX

SMALLPOX VACCINE

(NATIONAL) is suggested because:

- 1 Calves producing vaccine are kept under sanitary conditions
- 2 Careful technic in the vaccination of animals
- 3 Vaccine collected with aseptic care
- 4 Necropsy reports must show animals to have been in perfect health before vaccine is distributed
- 5 Bacteriologic tests are conducted to insure a vaccine free from pathogenic organisms
- 6 Potency and clinical tests made on each lot of National Smallpox Vaccine Virus insure an active and satisfactory product

KEEP SMALLPOX VACCINE COLD • HEAT KILLS IT

When you prescribe a liquid vaso-constrictor consider three points:

1

Prolonged Effectiveness

'Benzedrine Solution' produces a shrinkage which lasts 18 per cent longer than that produced by ephedrine

2

Minimum Secondary Reactions

On continued use 'Benzedrine Solution' produces practically no secondary vasomotor relaxation

3

Real Economy

'Benzedrine Solution' is one of the least expensive liquid vaso-constrictors

BENZEDRINE SOLUTION

Benzyl methyl carbinomine S K F, 1 per cent in liquid petrolatum with 1% of 1 per cent oil of lavender

Benzedrine is the registered trade mark for Smith Kline & French Laboratories brand of the substance whose descriptive name is benzyl methyl carbinamine

ANNALS OF INTERNAL MEDICINE

OFFICIAL PERIODICAL OF THE AMERICAN COLLEGE OF PHYSICIANS

Place of Publication—Prince and Lemon Sts, Lancaster, Pa

Editorial Office—University Hospital,
Baltimore, Md

Executive Office—4200 Pine Street,
Philadelphia, Pa

THE ANNALS OF INTERNAL MEDICINE is published by the American College of Physicians. The contents consist of contributions in the field of internal medicine, editorials, book reviews, and a section devoted to the affairs of the College.

MANUSCRIPTS All correspondence relating to the publication of papers and all books and monographs for review should be addressed to the editor. No manuscripts will be accepted without his consideration. Bibliographic references are to conform to the following:

4 DOE, J. E. What I know about it, Jr. Am Med Assoc, 1931, xcvi, 2006-2008

Six illustrations per article are allowed without cost to the author. Beyond this number the author must pay the actual cost of illustrations.

REPRINTS For each article published, there will be furnished gratis fifty reprints without covers. An order slip for additional reprints, with a table showing cost, will be sent with galley proof to each contributor. If additional reprints over the first fifty are ordered the order slip must be returned to the printer at the time corrected galley proofs are sent to the Editor.

REVIEWS The ANNALS will make an especial feature of the reviews of monographs and books bearing upon the field of internal medicine. Authors and publishers wishing to submit their material should send it to the editor. While obviously impossible to make extended reviews of all material, an acknowledgment of all books and monographs sent will be made by the department of reviews.

SUBSCRIPTION This periodical is issued monthly, new volumes beginning with the July number each year. Subscriptions may be by the volume or year, but the volume basis is especially recommended. Volumes will consist of approximately 1,400 pages. Subscription price per volume, or per annum, net postpaid: \$7.00, United States, Canada, Mexico, Cuba, and Alaska; \$7.50, other countries. Prices for back volumes or numbers furnished upon application. Single numbers, current volume, when available, \$1.00. Members of the American College of Physicians receive the ANNALS OF INTERNAL MEDICINE as a part of their membership. Checks should be drawn to the order of W. D. STROUD, Editor, Treasurer, and remitted through the Publication Office or the Executive Secretary's office.

BUSINESS CORRESPONDENCE All correspondence relating to business matters, advertising, subscriptions to the ANNALS, inquiries concerning membership in the American College of Physicians, et cetera, should be addressed to the Publication Office or to the Executive Secretary. Books and reprints presented to the College Library should be addressed to the Executive Secretary.

Acclaimed as a Masterpiece

Now comes the new second
revised edition of

Sir Thomas Lewis

DISEASES OF THE HEART

This new edition, appearing four years after publication of the original, brings the subject completely up to date and is written in the same clear, concise and interesting style which reviewers lauded in the first edition—

"It is a distinct contribution from the standpoint of subject matter, and its method of presentation will make many important facts readily available for practical use. This book is highly recommended to the students and practitioners of medicine. It is perhaps one of the most masterly presentations on this subject that has been presented to the profession. The subject of diseases of the heart is presented with a simplicity that is almost biblical in profundity and conciseness."

Journal of the American Medical Assn

"If the book consisted only of the chapters dealing with Heart Failure, Heart Strain, Work and Failure, and Treatment, it would still be one of the most valuable books written on heart disease in the past 25 years. The volume should find a place on the desk of every practitioner of medicine."

Virginia Medical Monthly

"He emphasizes as of extreme importance an understanding of cardiac failure and angina pectoris. The sections on the arrhythmias and disorders of the heartbeat cannot be surpassed. There is also a very instructive discussion of the differential diagnosis of fainting from vascular causes and of cardiac syncope as contrasted with unconsciousness from cerebral disease."

Northwest Medicine

"Packed with good sound clinical facts written in a manner that makes reading a pleasure. Certain passages, such as the description of cardiac asthma, deserve to be called classic."

Presenting the Interesting Results of Experiences Covering 20 Years in a Thyroid Clinic

Because of its authoritative character, this new book may be regarded as an almost indispensable reference book for all practitioners who are called upon to treat thyroid affections, either medically or surgically. It embodies, among other considerations, the principles of diagnosis and treatment, making it a practical text book. All the important findings and observations of the staff at the famous Massachusetts General Hospital during the past twenty years are here given, together with the significant work done elsewhere.

A concise summary and extensive bibliography at the end of each chapter contribute greatly to the utility of this work. Published March 1937. 602 pages. 73 charts and illustrations, \$6.00. J. P. LIPPINCOTT COMPANY, East Washington Square, Philadelphia, Pa.

AN IMPORTANT NEW PUBLICATION

NEW WORK

JUST READY

HEART FAILURE

By ARTHUR M. FISHBURG, M.D.

Associate in Medicine, Mount Sinai Hospital, New York City

Octavo, 788 pages, illustrated with 25 engravings Cloth, \$8.50, net

THIS BOOK is intended primarily for the general practitioner. It is a companion volume to the author's "Hypertension and Nephritis" and treats the circulation as that work treated the kidney. It portrays the recent advances in our knowledge in this field in such a way as to be directly applicable to the daily work of the physician. The author realizes with what limited facilities the general practitioner must usually carry on and has made every effort to supply him with a foundation of facts and principles which, although based largely on investigations in laboratory and clinic, forms the firm groundwork for intelligent practice.

The fundamental point of view is that afforded by the recent quantitative investigations of the circulation in health and disease which have proved so fruitful in bedside practice. Recent studies of cardiac output, velocity of blood flow, circulating blood volume, venous pressure, the respiratory volumes, and the gas contents and reaction of the arterial blood are all described in detail and are related directly to practice. The dominant point of view is always that of the practicing physician who must treat his patients with little instrumental aid, but who nevertheless wants to know the why and wherefore of what he does.

Accept this Invitation

EVEN without previous experience, YOU can make extremely accurate electrocardiograms with a minimum of manipulation and at small expense with the entirely new light-weight, low-priced G-E Electrocardiograph

You can obtain all of electrocardiography's recognized advantages from this compact, sturdy, dependable instrument—vitally important clinical information to aid materially in diagnosis and prognosis

You can depend upon the new G-E Electrocardiograph to give faithful, economical service in office, home, or hospital. It is substantial, light enough to be truly portable, heavy enough to assure durability. There are no gadgets or "trick" electrical circuits to complicate operation, instead, there is that all-too-rare combination of precision and simplicity that is the mark of sound engineering and years of experience in careful manufacturing.

To inspect and operate the G-E Electrocardiograph is to realize how valuable it would be to you in your daily practice (and, if we may say so, what an excellent investment it would be). Won't you accept a cordial invitation to actually make a cardiogram on it—in your own office—at your convenience—and without incurring any obligation? Detach and mail the convenient coupon—now

IN HEAD COLDS AND HAY FEVER

CONVENIENT AND
EFFECTIVE TREATMENT

THE instillation of nose drops is most effective when the patient is reclining with head thrown back. Yet how many of your patients will take the trouble—or, indeed, have the opportunity during the day—to administer nose drops in this manner?

On the other hand, 'Benzedrine Inhaler' is volatile. Its vasoconstrictive vapor diffuses throughout the rhinological tract. Consequently no uncomfortable or awkward positions are necessary for its correct administration.

Each tube is packed with benzyl methyl carbinamine, S K F 0.325 gm., oil of lavender, 0.097 gm., menthol, 0.032 gm. 'Benzedrine' is the registered trademark for S K F's nasal inhaler and for their brand of the substance whose descriptive name is benzyl methyl carbinamine.

BENZEDRINE INHALER

A VOLATILE VASOCONSTRICTOR

SMITH, KLINE & FRENCH LABORATORIES, PHILADELPHIA, PA

REGULATION

Regulation of the daily program, especially diet and exercise is beneficial, to normal bowel movement and in some cases of constipation serves as sufficient treatment. Others require additional aid to facilitate regular evacuation.

When an adjunct to diet and exercise is required, as it often is, Prolax provides a mild but effective

tive treatment. Its miscible properties make it easier to take and more effective than plain mineral oil. Further, by softening the feces Prolax induces large, well formed stools which are easy to evacuate. The five types of Prolax afford a choice of medication adaptable to the individual patient. Prolax Laboratories, Inc., Chicago

Prolax is a mechanical emulsion of pure liquid petrolatum (65% by volume) and agar agar. Accepted by the Council on Pharmacy and Chemistry of the American Medical Association for the treatment of constipation.

Prolax

Indicative

The nameplate on the Hindle is not the manufacturer's ordinary insignia, but a solid brass plate specially engraved with the owner's name. This may seem unimportant to proper operation of the instrument, but it is a wind straw that indicates the extreme care that Cambridge employs in designing and building *the vital parts which you cannot inspect*.

The Hindle has always been known for accuracy of tracing, dependability and ruggedness. While present-day models cannot be more accurate than the early Hindles upon which the art was developed in this country, they are far simpler to operate, more convenient to use. The Hindle is a "lifetime" instrument.

All-Electric models are made in stationary, mobile and portable types for hospitals, clinics and private offices.

Diabetic

LIVE LONGER TODAY

THE LIFE SPAN of the diabetic has been lengthened considerably following the discovery of Insulin and the growing knowledge of its use. There is, however, a definite responsibility on the part of the physician to educate the many new diabetics in the importance of proper diet and proper use of Insulin preparations.

The apparent increase in diabetes in recent years has been attributed to the modern manner of living, increased sugar consumption, overeating and lack of muscular exercise. With proper management the great majority of patients can be kept well-nourished, sugar-free, and at work.

Insulin Squibb is an aqueous solution of the active anti-diabetic principle obtained from pancreas. It is accurately assayed, uniformly potent, carefully purified, highly stable and remarkably free of pigmentary impurities and proteinous reaction-producing substances.

Insulin Squibb of the usual strengths is supplied in 5-cc and 10-cc vials.

Protamine Zinc Insulin, Squibb complies with the rigid specifications of the Insulin Committee, University of Toronto, under whose control it is manufactured and supplied. It is available in 10 cc vials. When this preparation is brought into uniform suspension, each cc contains 40 units of Insulin together with protamine and approximately 0.08 mg of zinc.

For adequate treatment of

PERNICIOUS ANEMIA

Lederle's "1 cc Concentrated Solution Liver Extract" offers these advantages

A high degree of therapeutic effectiveness—

A small volume for each injection—

A minimum of discomfort from each injection—

An individual dose container (additional safety)—

Economical treatment of the disease
—a given amount of active material injected being equivalent clinically to from 30 to 50 times that amount taken orally—

It provides for the use of large amounts of active material which are frequently required for the treatment of the nervous system changes—

Relatively long intervals, 7 to 20 or more days, between injections—

Supplied only in boxes of 3—1 cc vials

LEDERLE LABORATORIES, INC
30 ROCKEFELLER PLAZA NEW YORK, N Y

Illustration shows blood smear from patient who has received adequate liver therapy for a period of two years. Both the red and white blood cells are normal in contour and size. Hemoglobin is normal or above and platelets are abundant.

1 cc. CONCENTRATED SOLUTION LIVER EXTRACT

Lederle

'Amytal'

(ISO-AMYL ETHYL BARBITURIC ACID,
LILLY)

● Reserves of energy which are normally present in the body in health may be quickly dissipated by illness or even by insomnia. Just as an army unit must have sleep if a campaign is to proceed successfully, so the sick individual must be assured the

sleep he needs for restoration of nervous, nutritional, and other reserves.

Restful and refreshing sleep may be induced by 'Tablets 'Amytal''. A single 1 1/2-gram tablet will produce the desired somnifacient effect in the average adult.

Tablets 'Amytal' are supplied in 1/8-gram, 1/4-gram, 3/4-gram, and 1 1/2-gram sizes in bottles of 40 and 500 tablets.

ELI LILLY AND COMPANY

Principal Offices and Laboratories, Indianapolis, Indiana, U S A

Here's the METABOLISM APPARATUS For Scientific Research or Routine Examination

The Benedict-Roth meets all metabolism testing requirements accurately and simply. Mail the coupon below for illustrated circular.

Now you can get in a single machine a combination of qualities long considered desirable in Metabolism Apparatus: *accuracy* for scientific research, *simplicity* for office routine, *economy* for widespread general use. That apparatus is the Benedict-Roth.

Back of the machine itself lies twenty-seven years of Collins craftsmanship and experience in the field of respiration. Into the apparatus has gone the benefits of a rich scientific background of development at the Carnegie Nutrition Laboratory, plus fifteen years of experiment and improvement.

The result is a metabolism apparatus that is amazingly simple. With no motor, no vibration and no noise to influence the respiration record. Employed instead are Flutter Valves—quiet, easy-breathing, efficient.

The computation technique has been greatly simplified too by the use of Computation Charts developed at the Mayo Clinic. Accurate computations are made in 3 minutes—and you have a permanent record showing oxygen consumed, method of computation and the patient's B M R.

Mail the Coupon

If you'd like to see how simple it is to compute the Basal Metabolic Rate with the Benedict-Roth, let us send you a sample computation chart together with an illustrated circular. Just mail the coupon below.

One of a series of advertisements prepared and published by PARKE DAVIS & CO in behalf of the medical profession
This See Your Doctor campaign is running in the *Saturday Evening Post* and other leading magazines

Are two pairs of hands enough?

"OUR BABY will have every advantage"

Of course But are affection, the determination to give children "every advantage," parental devotion, enough?

No, frankly they are not The two pairs of hands of even the most conscientious parents are *not* enough to guide a child safely past the hazards that confront her The little body hasn't yet built up a very sturdy resistance against many of the disease-producing germs we all encounter every day of our lives She is susceptible to a whole group of illnesses that are visited almost solely upon children—the so-called "dis-

eases of childhood" Her diet, her hours of rest, her health habits—all have an important bearing on her future

That is why two pairs of parental hands are not enough A *third parent* should be added to the family circle That third parent is the doctor

To be sure, you are quick to get in touch with the doctor when your child is ill But isn't the youngster really entitled to more than that? Shouldn't she see the family doctor often enough to regard him not as a stranger but as a friend? And shouldn't he know about her previous illnesses and be familiar with her little whims and

how to get around them?

Then, too, the doctor should have the opportunity of giving her full benefit of modern *preventive* medicine—consultations about her growth and development, and protection against such diseases as small-pox, diphtheria, and whooping cough

He, too, should have hold of her little hand, guiding her along the road of health that is every child's right

NUTRITIONAL FACTORS IN GRAVES' DISEASE

By J H MEANS, F A C P, S HERTZ and J LERMAN,
Boston Massachusetts

THAT marked grades of malnutrition may result from thyrotoxicosis has been long known. In 1893 it was that Friedrich Muller¹ noted the paradox of weight loss in the face of increased food intake and concluded therefrom that there must be in this disease an increased rate of katabolism.

Whether or not weight loss or general wasting will occur in Graves' disease depends on whether the appetite increase causes sufficient increase in the ingestion of total calories to offset the increased combustion. Compensatory hyperorexia we may call it. The bank balance, in other words, is determined by the relation of amounts deposited to those withdrawn. In Graves' disease we not infrequently encounter weight losses of as much as 50 pounds or more.

Not only, however, may thyrotoxicosis cause malnutrition, but lately it has come to our attention that malnutrition may cause, or precipitate, thyrotoxicosis.

A few years ago one of us (S H) was impressed with the number of patients with toxic goiter who gave histories of having started their thyrotoxic symptoms at the conclusion of a reduction program for obesity. An overweight person would go on a low calory diet and after having lost the desired amount of weight would increase the diet, but find that weight loss continued, perhaps at an accelerated rate. Along with this, nervousness, tremor and other symptoms of thyrotoxicosis would make their appearance. In some of these cases thyroid had been used to augment weight reduction, but in others, mere calory restriction.

Interest having been aroused in this sequence of events, we began to be on the lookout for such cases. They have turned out to be numerous. The total to date is 35. In 14 of these the prethyrotoxic weight loss was occa-

* Presented at the St. Louis meeting of the American College of Physicians, April 21, 1937.

From the Thyroid Clinic of the Massachusetts General Hospital.

sioned by reduction cures and in the remainder it was due to a variety of conditions such as restriction of diet in the treatment of ulcer, ulcerative colitis, diabetes and other diseases leading to malnutrition

It seems to us that this series is too large not to be of significance. Episodes which activate thyrotoxicosis have long been recognized. Psychic traumata, prolonged infections, accidents or physiologic strains, such as puberty, pregnancy or the menopause, fall in this category. Now it seems that acute malnutrition can be added. How it operates, we are not prepared to say, but it is not known how any of the others operate for that matter. It may be associated with changes in blood chemistry or with vitamin or protein deficiency.

In approaching the problem of the moods which nutritional factors may play in the production of the clinical picture in Graves' disease it will be convenient to distinguish between what we may term general malnutrition due to total negative calory balance and more specific types of malnutrition, or deficiency due to absolute or relative shortage of specific dietary elements. Of general malnutrition, save insofar as it constitutes an indication for treatment, I need say nothing further, it being thoroughly familiar. Certain specific or special types of malnutrition, on the other hand, I believe can be discussed with some profit.

In this group of special forms of malnutrition let us consider first the *musculature*. Myasthenia is a common symptom in toxic goiter. Plummet,² Lahey³ and others have devised diagnostic tests to bring this symptom or sign into evidence. Actual muscle atrophy occurs less commonly, but in certain cases is very striking. Some years ago we⁴ reported a case in which there was a picture closely resembling progressive muscular atrophy in an advanced stage. The patient was also found to be suffering from toxic goiter. Cure of the latter by surgery was followed by recovery of the muscles. This is the most marked example of muscle atrophy we have seen in toxic goiter, but very often we encounter lesser grades with atrophy of the temporal, interossei or shoulder girdle muscles. Such atrophy is usually present in a patient who has been severely thyrotoxic over a long period of time and is therefore of prognostic significance. The exophthalmos, in certain types at least, may be a local expression of general muscle weakness. The degenerative changes in the striated recti muscles of the eye and the normal appearance of the smooth muscle of the eye, described by Askanazy,⁵ suggest a muscle imbalance which may explain exophthalmos. On the chemical side there is a disturbance in creatinine metabolism with creatinuria and, as shown by Shorr and Richardson⁶ a decreased creatine tolerance test.

The skeleton in certain cases shows marked decalcification. This is properly to be classed under specific forms of inanition. Aub and his co-workers⁷ in 1929 showed that the thyroid hormone causes a marked increase in the rate of withdrawal of calcium and phosphorus from the skeleton, without, however, in contrast to the parathyroid hormone, any sig-

nificant change in the blood levels of these elements. It is indeed in thyrotoxic persons that the highest levels of calcium and phosphorus excretion are to be found. This high excretion is a specific effect of the hyperthyroidism, not merely a feature of elevated general metabolism. (Aub et al¹)

FIG 1 Osteoporosis with compression fracture of a lumbar vertebra following thyrotoxicosis

found in cases of fever and leukemia with marked elevation in general metabolism, normal elimination of calcium.

The rate of decalcification of the skeleton in thyrotoxicosis will depend not alone on the rate of calcium loss, but upon the intake. Although the

increase in calcium excretion is great, it usually takes a long time for osteoporosis to become apparent. Patients with acute forms of toxic goiter usually get treated successfully before any marked grade of osteoporosis has been produced. The increased appetite probably causes an increased ingestion of calcium and offsets to some extent the process of bone wasting.

In a few cases of long-standing thyrotoxicosis, however, we have observed very marked osteoporosis, both in the spine and in long bones. In some of these cases symptoms have resulted, taking the form of deep aching pain in the extremities or back, and in one remarkable case there was a pathologic fracture of the body of a vertebra. This patient had been treated by us⁸ in 1919 for mild Graves' disease, then of three years' duration, by means of roentgen-ray therapy. She had improved somewhat, but, since she had not recovered completely, a subtotal thyroidectomy was done in March 1922. After that she was fairly well until August 1931, when while driving her car she was seized with sudden knife-like pain in the region of her lumbar spine. This persisted intensely and continuously for one and a half hours, then upon motion for three to four weeks and finally as tenderness in the lumbar region until December 1, 1931, when she returned to the hospital for study. Roentgen-ray examination showed marked decalcification of the entire spine and pelvis and a compression fracture of the first lumbar vertebra. The body was half its natural thickness and was irregular and mushroomed.

The patient was put on a high calcium diet with 5 drachms of calcium glycerophosphate and 30 drops of viosterol per day, under which regime her symptoms were quickly relieved. We have followed her since and although by roentgen-ray there is no great evidence of recalcification, the symptomatic result has been excellent.

Another striking example (a private patient of J. L.) is that of a woman of 58, who became bedridden as a result of long-standing thyrotoxicosis and cardiac failure. She showed a marked degree of osteoporosis. As a result of her semi-sitting position, she developed a dorsal kyphos and flaring of the lower ribs. The latter were exquisitely tender to pressure.

With removal of the thyroid, she has gradually assumed her normal activities and her heart is well compensated. Her kyphos has straightened considerably, the flaring of the rib margins is less and tenderness has disappeared. She is on an adequate diet with emphasis on milk, vegetables, cheese and meat.

In cases of long-standing thyrotoxicosis then, or even past thyrotoxicosis, in which pains in the spine or extremities are complained of, the possibility of osteoporosis should be given consideration and, if found, suitable treatment by a recalcifying regime instituted.

A shortage of iron is suggested in an impressive number of patients with thyrotoxicosis by the presence of nail changes of the sort characteristic of hypochromic anemia—that is to say spoon-shaped, brittle, lustreless and

longitudinally ridged—together with smooth tongues and gastric achlorhydria. Even when these signs are well marked, one usually finds but a slight degree of anemia. One patient recently, however, a woman of 58, presented symptoms of thyrotoxicosis, minimal eye signs and goiter, basal metabolic rate at the level of about plus 40 and along with all this, smooth tongue, spoon fingernails, achlorhydria, red count of 3.6 million and hemoglobin of 45 per cent. She was placed on both iodine and iron. She made a characteristic and good response symptomatically and metabolically to iodine, her basal metabolic rate falling to standard in nine days. She was continued on iodine for a year at the end of which time her basal metabolic rate was normal and she was symptom-free. The anemia also, in less than a month, rose to a red cell level of 6 million and hemoglobin of 75 per cent. Iron was then omitted. We presume that iron was responsible for the result. At the end of a year her blood picture showed a red cell count of 4.8 million and hemoglobin of 85 per cent.

Of late we have been interested in the question of avitaminosis in thyrotoxicosis. In the case of vitamin B₁, at least, Cowgill and his co-workers⁹ and others have shown that the need for vitamin increases in parallel fashion to the metabolic rate. Thus a person who had been receiving an adequate amount of vitamin B₁ during health might develop a deficiency on the same vitamin intake if he became thyrotoxic.

In view of these facts, two of us (S. H. and J. L.) administered vitamin B₁ in the form of Harris Yeast Powder to a small series of thyrotoxic patients and found that although it caused no change in basal metabolic rate, there was, coincident with its administration, a marked improvement in appetite and consequent gain in weight. Since that time we have employed treatment with yeast routinely in the preparation of thyrotoxic patients for operation. Although it is too early to draw a conclusion based on statistics of the effect of this maneuver on operative mortality, it is becoming increasingly clear that it is of value in improving general nutrition through the increase it causes in appetite. Its use is chiefly indicated in those patients whose appetite increase has been inadequate.

Shortage of vitamin B₁ may also play a more specific rôle in thyrotoxicosis. Weiss¹⁰ has shown that in alcoholics with cardiac insufficiency avitaminosis B₁ may play a rôle. It is quite possible, as he suggested to us, that it may also play a rôle in the cardiac insufficiency of thyrotoxicosis. Certainly one is more apt to see cardiac insufficiency in the malnourished than in the well nourished thyrotoxic patient. We recalled four recent striking examples as soon as Weiss mentioned the matter to us. One of these also had a moderate hypochromic anemia. Since iodine produces benefit in nearly any thyrotoxic patient, and since it is our practice not to withhold iodine in the thyrotoxic patient with cardiac insufficiency, we cannot say with certainty how much, if any, benefit to the heart vitamin B₁ administration has conferred per se. It will only be after large numbers have been treated that a dependable conclusion can be drawn.

Evidence of shortage of other vitamins has not been impressive. Scurvy we have not seen, but in one recent case in which thyrotoxicosis followed a grossly inadequate diet, night blindness became a striking symptom. It cleared up directly when an adequate diet was received. It may be interpreted as evidence of a shortage of vitamin A.

The chief point which we wish to make about all these matters, is that there is much more to the preparation of the thyrotoxic patient for operation than mere iodimization. The preparation, which we believe should be under the direction of the physician, but observed also by the surgeon, should include a positive attempt to improve general nutrition and relieve any specific deficiencies insofar as this is possible. Sometimes it will be the part of wisdom to defer operation, even though a good iodine response has been obtained, in order to meet more adequately a nutritional indication. The following case is a good example.

A 43 year old widowed supervisor of nurses, who had acute rheumatic fever at the age of 28, followed by mitral stenosis entered the medical ward February 16, 1936, with a story that for two years or more she had been running herself ragged, eating very little, taking a great excess of tea and coffee, sleeping badly, having marked anorexia and losing in 18 months some 25 pounds. She had been a thin, frail woman to start with and after the loss mentioned was markedly malnourished.

For two months prior to entry in addition there had been marked nervous irritability. At the time of entry she showed marked hyperirritability, slight bilateral exophthalmos, marked tremor, warm moist skin, tachycardia of 140, slight diffuse enlargement of the thyroid and a basal metabolic level of plus 30. Her heart showed the murmur characteristic of mitral stenosis, with normal rhythm. She weighed 106 pounds. Her tongue was sore and atrophic, but there was no anemia. Her red count was 5.0 million and her hemoglobin 90 per cent.

At this time one of us (J H M) made a note to the effect that she undoubtedly had exophthalmic goiter and that this appeared to have followed the development of a state of malnutrition also that although her thyrotoxicosis was mild she was a poor risk for surgery on at least three counts (1) because she had the complication of chronic rheumatic heart disease, (2) a very unstable psyche, and (3) a very severe grade of malnutrition.

She was given iodine and made a good response as far as symptoms went and her basal metabolic rate dropped to a normal level. Instead of operating at this point, however, it was felt wiser to send her home on iodine and high calory, high vitamin diet. She was given vitamin B in the form of Harris Yeast Tablets.

On March 19, 1936, she reentered, having gained seven pounds and become less nervous. A subtotal thyroidectomy was done on March 27, which she went through uneventfully and on April 4 her basal metabolic rate was minus 1.

She did well for about eight months, but then developed a mild recurrence of thyrotoxicosis which threw her heart into fibrillation. Iodine controlled the thyrotoxicosis adequately, but the fibrillation continued. In January of 1937 she went through a sharp attack of bronchopneumonia without thyrotoxic exacerbation or gross cardiac decompensation. Although it cannot be proved, our guess is that her course through thyroidectomy would have been far less smooth if she had been operated upon immediately after the establishment of iodimization.

In conclusion we should like to warn physicians and patients against too vigorous reduction cures for obesity, thyrotoxicosis may be induced thereby, and in the preparation of the thyrotoxic patient for operation we should like to urge that the possibility of nutritional disturbances be considered and, if found, that an attempt be made to correct them.

The manifestations of nutritional disturbance, which may be found in thyrotoxic patients, include, as well as general inanition, changes in musculature, skeleton, hematopoietic system and very likely in the heart and psyche. While these findings may be merely incidental and their causal relationship to thyrotoxicosis ascertainable only by an extensive statistical study we feel that they are of sufficient frequency to warrant consideration in the complete management of patients ill with Graves' disease.

The methods of correcting these defects include not only a high calory diet for relieving general malnutrition, but one high in vitamins and minerals as well. Vitamin B₁ may be of special significance as having appetite increasing proclivities, and also perhaps some special beneficial action upon cardiac function. We are now using Harris Yeast Tablets for this purpose. Pure vitamin B₁ preparations can be used when the indication seems urgent.

For the high calory intake the chief dependence should be placed upon carbohydrate. Excessive protein is undesirable because through its specific dynamic action protein raises metabolism. Carbohydrate, on the other hand, in large amounts is insurance against depletion of the glycogen stores of the liver and thus safeguards that organ. With regard to fat, there is no special indication that we know of. Fat may be given to whatever extent the patient's appetite demands.

We feel that there is good reason for regarding the malnourished thyrotoxic patients and the psychotic as well as those with cardiac insufficiency as poor operative risks. It is wise to get their weight curves at least started upward before permitting operation. This sometimes will require several weeks of pre-operative medical treatment. There is a tendency to rush thyrotoxic patients too fast to the surgeon. It is the physician's responsibility to see that this be not done. It is also his responsibility to avoid unnecessary delay in the securing of relief of thyrotoxicosis by operative intervention. Although it is desirable that he have certain definite routine procedures—the use of iodine, for example—it is also desirable that he study

each case as an individual problem and plan his actual therapeutic program to meet individual indications

A STUDY OF THE DIAGNOSIS AND TREATMENT OF LOBAR PNEUMONIA ACCORDING TO TYPES AND SPECIFIC SERUM THERAPY *

By JULIEN E. BENJAMIN, M D , F A C P , MARION BLANKENHORN, M D ,
JAMES M. RULGSEGGER, M D , and FANNIE A. SENIOR,
Cincinnati, Ohio

ALTHOUGH recent reports of successes in the diagnosis and treatment of the pneumonias, according to specific criteria, have been impressive, it can hardly be said that the medical world is committed to the procedures. There are several valid reasons why this is true. While there have been excellent results reported by reliable observers in the treatment of the acute pneumonias with specific serum, the technical difficulties involved in accurate typing, as well as the expense incurred in the use of curative serum, are the major objections raised, and the ones which have caused clinicians to approach the subject with hesitation. These two obstacles will be overcome only when public health facilities are more widely distributed, so that laboratories, where typing may be done day or night, are more conveniently located, also funds must be made available for the purchase of curative serum, so that rich and poor alike may have its advantages. At present this is not true even of all cities of major size, to say nothing of the rural districts. Another possible reason why serum has not been more generally employed in the treatment of pneumonia is because of the doubts as to its efficacy, which many clinicians still harbor. In many instances the reasons for their scepticism appear well founded, and they will be won over only when serum therapy has arrived at the stage of infallibility.

The technic incident to correct, accurate, and rapid typing by the Neufeld method has been represented by enthusiasts as being an essentially simple technic, capable of accomplishment in any physician's office where technical assistance exists. It is quite possible that this explains some of the disappointments experienced by many reliable clinicians who have attempted the procedure. There is one thing that stands out with great certainty, namely, that if typing is not reliably done, the results in the administration of serum are bound to be disappointing. Whereas in a majority of instances the Neufeld technic is accomplished with little or no difficulty, in a certain percentage of cases difficulties will be encountered, necessitating arduous and painstaking study as well as special technical skill for their correct solution. When organisms are few in number, media suitable for the growth of pneumococci must be available (Avery broth or mice) so that the technician may find the invading organism which might otherwise be missed. Complete typing should also be instituted routinely, as in many instances two or even three types of pneumococci may be found in the same sputum. This infor-

* Read at the St. Louis meeting of the American College of Physicians, April 21, 1937

mation while puzzling at times, is of aid in the prognosis as well as diagnosis. Only in laboratories equipped with facilities not only for direct typing, but also for the transplanting of cultures to mocc and broth media, are satisfactory reports obtained.

While it is true that lives have been saved by the administration of serum at any time during the course of the disease, the greatest saving of lives occurs in those individuals who are fortunate enough to contract a type of pneumonia for which curative serum is available, and who are treated shortly after the inception of the disease. It should be possible, in the not too distant future, through a process of health education, to arouse public interest to the necessity of calling for medical aid early in the course of severe, acute respiratory disease. For the present, at least, this is not true and we are forced to treat situations as they exist. Furthermore, the disease unfortunately attacks in largest numbers those of the laboring class, and of these, the majority live under adverse conditions. Quite naturally, medical aid is not sought so early by this large group as by those in the higher economic level, where the disease is far less common. Practically all of the reported data concerning the specific treatment of the pneumonias have emanated from medical centers or large public hospitals. Had it been necessary to rely on the statistics gathered from private hospitals or in private practice, advances in this important aspect of the disease would have been much slower.

Those who have been closely associated with this method must admit that it represents the greatest advance in the control of this deadly disease, which has been made since pneumonia was first described.

Under the careful directions of such well known clinicians as Bullowa, Finland, Cecil and others, the mortality rate for the early treated cases of the commoner and more frequent types of pneumonia has been reduced as much as 50 per cent of its former high figure. In the more malignant types, and in the late cases the mortality rates have also been appreciably reduced. It was possible at the Cincinnati General Hospital in the year 1935 to 1936 to report the first series of 50 consecutive cases of Type I pneumonia treated within 96 hours of onset, without a single death.¹ These results were accomplished under anything but perfect conditions. The patients were inadequately nursed, the wards were considerably overcrowded, the patients were of the indigent class, many of them alcoholics. There was at hand, however, the setup for excellent laboratory work, and the enthusiasm for prompt and unrelenting administration of serum. We are now in our third year of study of the lobar pneumonias, according to this method. It is a critical analysis of some of our observations during the past 16 months which forms the basis of this discussion.

There are included in this study only the lobar pneumonias, with but few exceptions occurring in adults. It is primarily intended as a critical appraisal of the beneficial effects of concentrated specific curative serum in

patients whose pneumonic symptoms have existed 96 hours or less*. The treatment was instituted on the basis of Neufeld typing of sputum, mouse transplants and broth cultures. Commercial sera † for Types I, II, V, VII and VIII were used. There was also available, through the generous offer of the Littauer Pneumonia Fund, Harlem Hospital, New York City, serum for Types VI, XIV and XVIII. Blood cultures were taken in each instance, repeated when indicated, and the colony count followed.

The incidence of lobar pneumonia is quite high in Cincinnati. Morbidity rates are practically impossible to obtain, but each year there are more than 300 deaths attributed to this type of the disease, representing a mortality of 75.3 per 100,000 population. For the 16 months, October 1, 1935 to February 1, 1937, there were received at the Cincinnati General Hospital 485 cases (Table 1).

TABLE I
Cincinnati General Hospital
Incidence of Color, Sex, and Death Rates in Lobar Pneumonia
October 1, 1935 to February 1, 1937

| | No. of Cases | Deaths | Per Cent |
|---------|--------------|--------|----------|
| White | 245 | 60 | 24.53 |
| Colored | 240 | 62 | 25.83 |
| Males | 344 | 79 | 22.96 |
| Females | 141 | 43 | 30.49 |
| Total | 485 | 122 | 25.15 |

Almost an equal number of white and colored patients were examined and treated, and they died in about the same proportion. There was a crude mortality rate of 25 per cent as against a crude rate of 30 to 50 per cent over a period of six years, studied by Schiff² prior to the general use of type specific serum.

The distribution of cases according to age groups is shown in table 2. It is noteworthy that although only 42 per cent of the total number appeared after the fourth decade, 67 per cent of the deaths occurred during those years.

* The time interval of 96 hours has been arbitrarily selected, because of the possibility of a spontaneous crisis occurring after that time. Our criteria for establishing the diagnosis of lobar pneumonia have been:

- 1 Typical acute cases (early)
 - (a) Sudden onset—chill, pain, fever, cough, rusty sputum
 - (b) Typing of sputum
- 2 Atypical and late cases
 - (a) History upper respiratory infection with sudden change as under (a) above
 - (b) Physical examination indicating consolidation
 - (c) Typing of sputum
 - (d) Roentgen-ray in all doubtful cases

In each instance, the subsequent findings on physical examination were always relied on as corroborative evidence of the existence of pneumonic consolidation. Further, more than one clinician examined each patient.

† One kind of serum was used throughout the investigation.

TABLE II
Cincinnati General Hospital
Incidence of Age and Death Rates in Lobar Pneumonia
October 1, 1935 to February 1, 1937

| Decade | Number of cases | Percentage of incidence | Number of deaths | Percentage of total deaths | Percentage of deaths by decade |
|--------|-----------------------|-------------------------------|------------------------|----------------------------------|--------------------------------------|
| 0-9 | 9 | 1.9 | 1 | 0.8 | 11.1 |
| 10-19 | 50 | 10.3 | 4 | 3.3 | 8.0 |
| 20-29 | 114 | 23.5 | 14 | 11.5 | 12.3 |
| 30-39 | 104 | 21.0 | 22 | 18.0 | 21.5 |
| 40-49 | 96 | 19.8 | 36 | 29.5 | 37.5 |
| 50-59 | 58 | 12.0 | 23 | 18.9 | 39.7 |
| 60-69 | 40 | 8.3 | 14 | 11.5 | 35.0 |
| 70-79 | 13 | 2.6 | 7 | 5.7 | 53.8 |
| 80- | 1 | 0.3 | 1 | 0.8 | 100.0 |
| Total | 485 | | 122 | | |

In table 3 the cases are grouped according to serological types. Type I, the so-called "typical pneumonia," was responsible for 32 per cent of the entire group. Adding to this number, those other cases of the types for which curative serum exists (I, II, V, VII, and VIII), brings out the fact that for 66 per cent of the patients in this series appropriate curative serum was available.

Since only early cases were treated energetically with serum, a very considerable number of these patients did not receive this form of treatment. Of interest, however, are the results of serum treatment in some of these types.

We have worked on the thesis that there is no arbitrary dosage of serum in pneumonia, since so many factors must be evaluated in the treatment of the individual case. We have, however, set a certain minimal standard or range of dosage for each of the treatable types. These are Type I, 60-80,000 units, Type II, 100-120,000 units, Type V, 80-100,000, Type VII, 60-80,000 units, and Type VIII, 60-80,000 units. All of the "treated" patients received at least these amounts of serum intravenously. The initial dose consisted usually of 20,000 units, although in some cases it was only 10,000. The remainder of the minimal standard dosage was given at two hour intervals, each subsequent dose varying from 40,000 to 80,000 units. If blood cultures proved to be positive, from 60,000 to 100,000 additional units were administered, provided that the desired clinical effect had not intervened meanwhile.

Type I It has been shown conclusively that specific serum reduces the mortality in pneumonia due to Type I pneumococcus^{1,3}. While this is of the greatest importance, it is not the only criterion of the efficacy of serum. It is of equal interest to observe the effect of serum on the course of the disease in each patient. The uniformity with which rapid clinical improvement may be correlated with the administration of serum is of help, not only

TABLE III
Cincinnati General Hospital
Incidence of Types and Deaths in Lobar Pneumonia
October 1, 1935 to February 1, 1937

| Type | No of Cases | Deaths |

| Total | 485 | 122 |
| Crude mortality | | 25.15% |

in evaluating the efficacy of this agent, but also in defining the limits of its usefulness. Therefore, these criteria will be briefly discussed.

In table 4 a comparison of serum treated and non-serum treated cases is shown. The reduction in the death rate was striking. The crude mortality holds for different seasons, according to age, sex, and the presence or absence of bacteremia, and with respect to the extent of the pulmonary lesion. Our series shows that the mortality rate for all types not treated with serum amounted to 31.5 per cent. It is also apparent that contrary to popular belief, Type I pneumonia is not a relatively mild type of infection, since in our series the mortality rate for the untreated cases was 26.5 per cent. The early serum treated cases of Type I had a mortality rate of only 4.11 per cent.

The effect of the serum on the course of the disease is no less impressive. Almost all of the patients favorably affected were much more comfortable within two to three hours after serum administration, and crisis was com-

plete or nearly so within 24 to 36 hours. While actual crisis was observed as frequently in the untreated patients who survived, undoubtedly its onset was materially hastened in those receiving serum. Examining for a moment those cases of Type I considered therapeutic failures, the following facts are revealed:

TABLE IV
Cincinnati General Hospital
Comparative Mortality in Serum and Non-Serum Treated Cases
October 1, 1935 to February 1, 1937

| Type | Serum Treated within 96 hrs | | | Others * | | |
|---------|-----------------------------|--------|------------|--------------|--------|------------|
| | No. of Cases | Deaths | Death Rate | No. of Cases | Deaths | Death Rate |
| I | 73 | 3 | 4.1% | 83 | 22 | 26.5% |
| II | 26 | 8 | 30.7% | 26 | 9 | 34.6% |
| V | 11 | 2 | 18.1% | 36 | 11 | 30.5% |
| VII | 18 | 0 | | 25 | 6 | 24.0% |
| VIII | 8 | 0 | | 22 | 3 | 13.6% |
| † XIV | 2 | 0 | | 4 | 3 | 75.0% |
| † XVIII | 1 | 0 | | 5 | 1 | 20.0% |
| Total | 139 | 13 | 9.3% | 201 | 55 | 27.3% |

* A few of these patients received some serum, late in the disease, for experimental purposes.

† Obtained through the courtesy of the Littauer Pneumonia Fund, Harlem Hospital, New York City (Dr. Jesse G. M. Bullock).

Case 1 White, male, aged 78, admitted on the fourth day of the disease, with consolidation involving the right upper lobe. There was a history of previous coronary thrombosis, and evidence of auricular fibrillation. Marked nitrogen retention. White count 3,200 and later 1,900. Bacteremia of high degree. Died same day serum was given. He received 100,000 units.

Case 2 White, male, aged 65, admitted to the hospital with delirium tremens, and supposedly developed lobar pneumonia in the hospital. Leukocyte count 7,900. This man died with symptoms and signs of acute cardiac failure. There was also a question of beri-beri. He probably had had pneumonia longer than estimated. His death occurred on the same day that serum (118,000 units) was given. Necropsy revealed extensive empyema.

Case 3 White, male, aged 49. Second day of the disease. Blood culture positive after 100,000 units. Leukocyte count 6,500. He died the day after serum therapy. Doubtless, this patient should have received more serum.

The first two cases probably represent the irreducible minimum, since a certain number of derelicts and patients with severe degenerative diseases will inevitably succumb to the ravages of pneumonia, as the precipitating cause of their demise.

Whether or not a simpler and less drastic method of introducing antibody is suggested in years to come, we now have at our command a most reliable, specific, therapeutic agent to combat effectively that type of pneumonia which affects by far the largest number of people.

Other Types There is ample proof that specific serum is a reliable therapeutic agent in several other types besides type I. Certain features in

some of the types present minor difficulties, which have not been entirely obviated. In addition, the remaining 31 types, although their distribution is uneven, do not concentrate in any type in sufficiently large numbers to permit of reliable analysis. Caution must be observed in making deductions in so important a subject, with a relatively small number of cases. With this in mind, instead of subjecting each of the Types II, V, VII, VIII, XIV and XVIII * (the only other ones for which therapeutic serum is available) to critical analysis at this time it is of interest to consider the results obtained in these types considered together. Table 4 is valuable in this respect since it illustrates the saving in lives possible with this treatment. The numbers are sufficiently large to be significant. It is noteworthy that the mortality is three times as great in those patients who were not serum treated, as in those receiving serum.

Type II pneumonia is for us a difficult problem. Data at hand, gathered from the study of 52 cases indicate a comparable death rate of 30 and 34 per cent respectively, in cases treated specifically and non-specifically. In the final analysis it appears that in each unsuccessfully treated case, insufficient quantities of serum were given. The dose of serum for this type may ultimately be found to be three or more times the amount required for other types. In Finland's experience 200-300,000 units were necessary.⁴

Type V, it will be recalled, was the original Avery Type IIa. Nine per cent of our series fell into this type, a total of 47 cases. Of this number 36 were seen later than 96 hours after onset of their illness. None of these received serum and 11 of them died (30.5 per cent). Of 11 patients treated with serum earlier than 96 hours, only 2 died (18 per cent). Thus Type V is a pneumonia of high virulence when neglected, and quite amenable to specific therapy.

Type VII is often a fairly severe type of pneumonia which yields quite satisfactorily to serum administration. It is almost as prevalent as Type V. Of 18 consecutive cases treated early, not one succumbed, as against 6 deaths in 25 untreated cases (24 per cent).

Type VIII, related immunologically to Type III, is likewise favorably affected by serum therapy as far as anyone may judge from a small number of cases (30). No deaths occurred in the eight cases treated within 96 hours of the onset of pneumonia, there were three deaths among the 22 cases treated symptomatically. This type of the disease is, generally speaking, of the mild kind, if there be such in pneumonia, since the mortality rate was only 13 per cent for patients receiving no serum.

Bacteremia The importance of determining whether or not a blood stream infection is present, early in the course of pneumonia, cannot be overemphasized. No single factor influences the outcome so directly. The death rate in patients having bacteremia is exceedingly high. While the numbers here presented are not large, owing to the fact that we have taken

TABLE V
Influence of Bacteremia

| Type | Cases with <i>Positive</i> Blood Culture | | Cases with <i>Negative</i> Blood Culture | |
|-------|--|-----------------|--|-----------------|
| | Number | Deaths | Number | Deaths |
| I | 11 ⁵ | 9 ³ | 29 ¹⁵ | 1 |
| II | 11 ⁴ | 8 ³ | 19 ¹⁴ | 3 ³ |
| III | 10 | 10 | 23 | 5 |
| V | 7 ² | 4 ¹ | 7 ² | 0 |
| VII | 4 ³ | 0 | 18 ⁸ | 1 |
| VIII | 6 ³ | 2 | 9 ¹ | 1 |
| Total | 49 ¹⁷ | 33 ⁷ | 105 ⁴¹ | 11 ³ |

Superscript represents serum treated cases within 96 hrs

| | |
|--|-------|
| Death Rate—Cases with positive blood culture | 67.3% |
| Cases with negative blood culture | 10.4% |
| Serum treated cases with pos. Bl. Cl. | 41.1% |
| Non-Serum treated cases with pos. Bl. Cl. | 81.0% |
| Serum treated cases with neg. Bl. Cl. | 7.3% |
| Non-Serum treated cases with neg. Bl. Cl. | 12.3% |

blood cultures routinely only since October 1, 1936, it is noteworthy that of 49 patients with positive blood cultures who did not receive serum, 81 per cent died. On the other hand of 17 patients with bacteremia who received serum within 96 hours of the onset of their illness, 41 per cent died. Undoubtedly this percentage is susceptible to considerable further reduction. We believe that such cases require two to three times the quantity of serum ordinarily administered. Further, the treatment must be continued until the blood is sterile. The importance of blood culture determination early in the disease is only second to correct typing of sputum, the one to determine specific diagnosis, the other as a guide to dosage of serum.

There is abundant evidence also that complications are related to the presence of bacteremia. During the past six months we have studied more intensively the influence of blood stream infection on the general course of the disease. In reviewing the commoner complications of the pneumonias for the period October 1936 to February 1937 the data obtained (table 6)

TABLE VI
Complications
October 1, 1936–February 1, 1937

| | Bacteremic | Non-Bacteremic |
|-------------------|------------|----------------|
| Empyema | 8 | 2 |
| Meningitis | 5 | 1 |
| Endocarditis | 4 | 0 |
| Pyarthrosis | 2 | 0 |
| Pericarditis | 1 | 1 |
| Lung Abscess | 1 | 2 |
| Pleural Effusion | 0 | 4 |
| Otitis Media | 6 | 0 |
| Thrombo Phlebitis | 0 | 1 |
| Total | 21 | 12 |

indicate in an interesting manner that the serious complications (empyema-meningitis-endocarditis) occur more frequently in the bacteremic cases

DISCUSSION OF SERUM THERAPY

The importance of giving adequate amounts of serum relentlessly until definite signs of improvement appear, cannot be overemphasized. The introduction into the blood stream of foreign protein in such quantities has produced very few unfavorable reactions. Indeed we have been amazed at the negligible number of thermal reactions and instances of serum sickness. This was doubtless due to the fact that the new concentrated and highly purified therapeutic serum was used. In all we observed 23 cases of serum sickness, and 19 cases which showed immediate reactions to serum, 8 slight, 9 moderate, and 2 severe. In one instance of a severe reaction, the use of serum was possibly contraindicated by a mildly positive skin test to horse serum.

In almost all favorable cases, very soon after the administration of serum, the patient's general condition improves. The cyanosis becomes less, the pulse rate usually falls and respiration appears less arduous. Then follows gradually a lowering of temperature, amelioration of other symptoms and within a few days the patient returns to a normal condition. What is equally important is that there is rarely extension of the lung lesion. The detoxifying effect of serum is frequently prompt and startling. Further, its sterilizing effect on bacteremia is worthy of note.

Effect on Resolution While the administration of serum causes no change in the rate of resolution of affected lung tissues, there is no evidence that this process is interfered with, or delayed. Certainly those individuals successfully treated remain in the hospital for a much shorter time than those non-serum treated. The days of intense suffering are also materially reduced.

Effect on Mortality The final test of the effectiveness of immune serum must rest on the evidence concerning the saving of lives. While the studies reported herewith do not represent a very large number of cases, the results compare most favorably with those reported by other observers. Undoubtedly the saving in lives is greatest in Type I infections, but in the other types as well the lowering of mortality rates of serum treated cases as against non-serum treated cases, is definite. It is not too radical to conclude that "no patient with Type I infection who dies without the early intravenous administration of large doses of Type I serum, can be said to have received the best treatment."⁵ There is abundant evidence that potent immune serum exists for types which together comprise 65 per cent of all lobar pneumonia. It is hardly adequate medical treatment if so many lives continue to be needlessly sacrificed.

According to Rogers,¹ there occur, annually in Ohio, in the vicinity of 3,000 deaths from lobar pneumonia, indicating about 12,000 cases. About

96 per cent of all cases of "lobar pneumonia" are pneumococcal in origin. Of the 12,000 cases 65 per cent, or 7,800 cases, may be assumed to be due to Type I, II, V, VII, or VIII. On the basis of our knowledge of the potential effect of serum, we find that 1,400 lives might be saved, a reduction of 46 per cent in the mortality from this disease. Although it is improbable for a variety of reasons that this goal can be attained in the near future, nevertheless we should be urged on by the fact that there exist today, therapeutic agents which make this achievement possible.

The difficulties in our path are largely those of lay education and public health organization. It is gratifying to note that the states of New York, Massachusetts, Connecticut and Michigan are now well organized in their approach to the prevention and specific treatment of the pneumonias. Facilities for prompt typing of sputum as well as appropriations for the purchase of serum for the indigent, exist as an important plank in their campaigns against preventable and curable diseases. While only specific serum for Type I and II is usually available, one of the states has already increased its funds so as to include Types V, VII, and VIII.

This represents a progressive attitude on the part of public health officials. Undoubtedly great reduction in pneumonia mortality will be the result of their efforts. The educational pamphlets distributed to the public and profession by these officials will go far toward rounding out their program of prevention.

That the pneumonias in a large percentage of instances are readily communicable from one individual to another is an accepted fact. For this reason, the enforcement of the same precautions as are taken in the effort to control the spread of other contagious disease is justifiable. Compulsory notification should be instituted without delay. Each case of pneumonia should be regarded as a focus for the spread of the infection, and the care of each patient should include those measures which have been found serviceable in other communicable diseases. We were convinced of the need of segregating patients in cubicles rather than treating them in the open ward and of requiring physicians and nurses to observe the same precautions in caring for these patients as are usual in contagious disease wards. The wearing of gowns and masks and washing hands after each examination or treatment should be strictly enforced. Before instituting these procedures, not a few instances of cross infection occurred in our ward. The type of pneumonia contracted was frequently traceable to patients in nearby beds. There were also encountered cases in individuals who had visited pneumonia patients in the hospital. We have likewise records of two or more members of a family contracting pneumonia of the same type in succession. Recently Finland and Tilghman⁶ emphasized this fact and in their conclusions stated that bacteriologic studies made on members of households in which multiple cases of pneumococcus infection were observed, revealed a high incidence of carriers of the type of pneumococcus responsible for the infections in the relatives.

CONCLUSIONS

1 Of 485 typed cases of lobar pneumonia observed during a 16 month interval, 66 per cent fall within those types for which therapeutic serum is available

2 Early diagnosis of the exact etiological agent of lobar pneumonia is of paramount importance in serum therapy, blood cultures are necessary, frequently as diagnostic procedures, and always for prognosis

3 In comparable series of Type I patients, the mortality among those receiving serum within 96 hours of the onset of the disease was 4.1 per cent whereas 26.5 per cent of the non-serum treated patients died. In much smaller groups of patients similarly striking results were shown after the use of specific serum in Type VII and Type VIII pneumonia respectively

4 Specific serum treatment of all patients (Types I, II, V, VII, VIII, XIV and XVIII) seen within 96 hours of onset, resulted in a death rate of 9.3 per cent. Of the group not treated with a specific serum 27 per cent died

5 Bacteremia influences the prognosis unfavorably and is an indication for the administration of larger quantities of serum

6 The intravenous administration of refined, concentrated antipneumococcus horse serum is not fraught with severe, untoward reactions in the non-sensitive patient

7 Lobar pneumonia is a contagious disease and as such should be treated as a public health problem

SOME CLINICAL CAPRICES OF HODGKIN'S DISEASE

By WILLIAM S MIDDLETON, F A C P, *Madison, Wisconsin*

IN 1856 Samuel Wilks¹ wrote, "It is only to be lamented that Dr Hodgkin did not affix a distinct name to the disease, for by so doing I should not have experienced so long an ignorance (which I believe I share with many others) of a very remarkable class of cases, a recognition of which would have guided both myself and others to an explanation of some more recent instances coming under our notice" Nine years later Wilks² critically analyzed Hodgkin's materials³ and found that the latter had included other pathologic conditions than the one bearing his name through the magnanimous gesture of the former An interesting confirmation of this position was afforded by Fox's reexamination of the original tissues⁴ after an interval of 97 years from the time of their preservation

If confusion marked the histologic definition of Hodgkin's disease, its clinical delineation could scarcely be expected to escape similar difficulties Eventually there have been evolved diagnostic criteria and clinical features that typify the classical case Briefly stated, Hodgkin's disease occurs characteristically in the age period between 18 and 35 years with a predilection for the male sex in the proportion of two to one Two secondary and minor peaks are observed in the incidence curves, namely between five and ten years for both sexes and at the menopause for women Insidiously the lymph nodes of a single group, as the posterior cervical chain, become involved in a singular manner They are painless and non-sensitive unless a nerve trunk be involved Their firmness varies with the cellular content, supporting framework and capsular tension As a rule it approximates the consistency of cartilage Until late in the course of the untreated subject the affected nodes remain discrete and unattached to the overlying or the underlying structures Redness and increased temperature of the skin are rarely observed over the involved nodes Suppuration is very unusual In the cervical involvement eventually a characteristic pyramidal conformation results with the largest nodes at the base above the clavicle and the smallest ones in the apex at the angle of the jaw⁵ Eventually the process becomes bilateral, involves the lymphoid system widely through the body and includes the liver and the spleen in its pathologic changes In general the involvement of the lymphoid tissues of the body is progressive but marked remissions with reduction in their bulk may occur spontaneously from time to time

The local symptoms of Hodgkin's disease will depend on the site of the lymphadenopathy They may include among other manifestations, paresthesias and pain from neural pressure, Horner's syndrome from sympathetic destruction, cyanosis and edema from interference with venous return

*Read at the St Louis meeting of the American College of Physicians, April 21, 1937
From the Department of Medicine, University of Wisconsin

(lymph stasis contributing), dyspnea, cough superior cyanosis and dysphagia from mediastinal involvement. Jaundice may result from common duct obstruction through lymphadenopathy or from direct invasion of the liver by the cellular reaction of the disease. Splenomegaly is a common manifestation and its degree may induce independent symptoms of dragging discomfort, early satiety and constipation. Hepatomegaly may lead to right-sided abdominal pain. Certain skin manifestations are encountered. Among these, brownish pigmentation and intractable pruritus take prominent places. A wide diversity of symptoms may result from the involvement of other organs or tissues.

The constitutional reactions of Hodgkin's disease are extremely variable. Fever occurs at some time in the course of practically all cases. In some it appears early and remains a prominent detail of the composite clinical picture. In others its appearance may be deferred to constitute a serious portent. Its form likewise is variable. Remittent fever is the rule but occasionally a continuous type is encountered. Finally there is a singular form of fever in this disease that is designated by the names of its several observers: Murchison,⁶ or Pel'-Ebsen.⁸ Such a fever is marked by bouts of remittent or continuous pyrexia and intermissions of apyrexia. Chills and sweats of varying degrees may attend the fever. While classically a remarkable regularity in the time and the degree of the febrile episodes as well as in the duration of the afebrile intervals may be anticipated, any recurring fever may assume a diagnostic significance in the presence of other clinical evidences of Hodgkin's disease. Tachycardia may occur independently, but usually parallels the febrile course. Cachexia appears sooner or later in most patients with Hodgkin's disease unless serious obstructive symptoms unduly shorten the course. Furthermore pallor and wasting are grave prognostic details.

The laboratory findings include the blood picture so adequately discussed by Bunting.^{9, 10} Beyond a question of doubt in the hands of expert hematologists his criteria offer a differential diagnostic aid of great usefulness in the presence of progressive lymph node involvement, but in the wider sense the transition from an early phase of lymphoid resistance to a late one of lymphoid paralysis affords a prognostic index of surpassing utility provided the blood has been followed consecutively with other clinical observations. An anemia of the hypochromic type is the rule and it may assume profound degrees. The platelets are increased in virtually all cases. The basal metabolic rate is elevated during the periods of clinical activity of Hodgkin's disease¹¹, but there is apparently no diagnostic implication in this observation. The ultimate diagnosis may in many cases rest upon the histologic examination of the affected lymph node. Certainly Gordon's studies upon the central nervous changes incident to the intracerebral and intravenous injections of emulsified lymph nodes¹² offer no material diagnostic assistance. The high incidence of mediastinal involvement¹³ indi-

cates the advisability of roentgenoscopy and roentgenography in the investigation of this field. Likewise roentgenograms of other suspected areas, as the bony framework, gastrointestinal system and so forth, may extend the clinical prospect.

Few clinical conditions conform more closely to the accepted descriptions than does the typical case of Hodgkin's disease. At the same time there is no disease with a more diversified range of clinical expression. On one hand these variants may result from the overwhelmingly predominant emphasis upon some common or uncommon feature of the disease. Again some clinical vagary may so distort the picture as to render its diagnosis extremely difficult.

With this thought in mind a series of such instances of Hodgkin's disease has been briefly digested.

I AGE

Case 1 A white female, aged 6, complained chiefly of coughing. This cough had persisted for five months without expectoration. There had been no weight loss but progressive weakness had been observed and breathing had become somewhat difficult. Two months after the onset and concurrent with an apparent respiratory infection, enlargement at the base of the neck on the left side was observed.

The physical examination established the presence of firm, movable supraclavicular nodes on the left with dullness and bronchial breath sounds in the upper left chest. Below this, anteriorly, the breath sounds were absent but posteriorly the breath sounds were within normal range. The blood count was significant only in the polymorphonuclear neutrophilia of 87 per cent of a total leukocyte count of 8,150. Roentgenogram of the chest showed a mediastinal mass with extension to the left. Two months after the first admission the patient was reexamined and at this time fluid had appeared in the left thoracic cavity, and it proved to be serosanguinous upon aspiration.

Case 2 A white male, aged 84, entered with a chief complaint of "tumor of the neck," which condition was dated to a sore throat four years previously when a small purplish tumor was observed in the right tonsil. The occurrence of lymph node enlargement in the right side of the neck led to radium treatment of the tumor of the tonsil and surgical removal of the cervical masses. A year and a half later tumors recurred in the right side of the neck and later the left side was likewise affected. These progressed slowly and were removed surgically. Following their extirpation, roentgen-ray treatment was renewed, but after its discontinuance the tumors reappeared slowly and painlessly. The general health remained unimpaired and there was slight weight loss.

The physical examination was significant only in the definition of the cervical lymphadenopathy involving the submaxillary and the anterior and posterior cervical chains. These nodes were firm in consistency and irregular in shape. There was apparent attachment to the underlying structures but none to the overlying skin.

By reason of the extremes of age in Cases 1 and 2, six and 84 years respectively, Hodgkin's disease had not been a primary consideration and only upon biopsy was such a diagnosis possible.

II SKIN MANIFESTATIONS

A Pruritus

Case 3 A white male, aged 28, complained of shortness of breath. His trouble was dated to eight months ago when a troublesome itching developed over the entire body. Six weeks later a respiratory infection supervened and there was a relapse a week after its onset, so that the patient remained in bed for a week and a half. Following this, weakness persisted and vomiting became intractable. Four months after the onset, he went to the Rocky Mountains for a rest and fluid was found in the left pleural cavity. After an aspiration, the diagnosis of Hodgkin's disease was made by the biopsy of a cervical lymph node. The succeeding course was one of recurrent accumulation of fluid in the pleural cavity with progressive loss of ground.

The skin was particularly interesting in the encrusted, excoriated areas over the back and legs and the scarring and pigmentation at the site of old lesions. Lymphadenopathy of a characteristic order, splenomegaly and hepatomegaly with the evidence of mediastinal involvement ultimately completed the picture.

Pruritus is a well recognized manifestation of Hodgkin's disease. Not infrequently it succeeds other and more clearly defined evidences of the condition, but occasionally as in Case 3 pruritus may anticipate the characteristic lymphoid changes by a considerable period.

B Ulceration

Case 4 A white female, aged 26, experienced considerable difficulty in the healing of a wound subsequent to a biopsy in the left axilla three and a half years before admission. This study confirmed the diagnosis of Hodgkin's disease but subsequently cervical lymphadenopathy appeared and the characteristic pyramid of discrete, non-tender lymph nodes was noted. Extended roentgen-ray treatment was thereafter applied in both cervical and the left axillary regions. The left breast became involved and extension from the original site was suspected. With slight fluctuations the process was well controlled by roentgen-therapy, but in the intervals between treatment, sharp accessions in the process occurred in the above described areas. Twenty-seven months after the first observation in this hospital, the patient noticed a draining sinus in the right upper chest and there was progressive enlargement of the involved lymph nodes. Three subsequent admissions over the following 14 months showed some extension of the ulceration in the right infraclavicular region. This ulceration had a gray, dirty base with abrupt margins. A second supraclavicular sinus appeared. Eventually these two areas joined to form a single ulcer 10 by 12.5 cm. and the edges showed slight sluggish granulation.

Suppuration of the lymph nodes in Hodgkin's disease with resultant sinuses is unusual. Indolent ulcers on this basis are even rarer. Just what part roentgen-therapy played in the sequence of events in Case 4 is impossible to state. Unfortunately the earlier experience of the patient led her to refuse a biopsy of the margin and the base of the ulcer that might well have fixed the etiologic responsibility.

C Breast

Case 5 A white female, aged 58, complained of a lump in the breast which had been noted for a year. At first there had been a small lump the size of a hickory nut in the right axilla and this had grown to such an extent six months previously.

that she consulted a physician who advised amputation of the breast. The size of the mass alone inconvenienced the patient.

Through careful examination it became apparent the mass had arisen in the right axilla as stated by the patient and extended beyond the anterior axilla leading into the upper and outer segment of the breast and lying superficially to the pectoralis major. Posteriorly the mass extended across the axillary line to elevate the skin over the latissimus dorsi. It did not involve the apex of the axilla. In consistency it was firm but not of stony hardness. It was not attached to the skin nor to the deeper tissues. It was nontender and there was no general lymphadenopathy (figure 1).

Under general anesthesia the mass in the right axilla was resected and proved to be Hodgkin's disease.

FIG 1 Hodgkin's disease of the axillary lymph nodes erroneously diagnosed tumor of the breast (Case 5)

Particular interest attaches to Case 5 by reason of the mistaken diagnosis of a tumor of the breast, whereas an accurate history supported by a careful physical examination clearly traced the mass to its original site in the right axilla

III NEURAL INVOLVEMENT

A Neuritis

Case 6 A white male, aged 36, complained of pain in the right leg. For eight to ten weeks prior to admission the patient had experienced a constant dull ache in the calf of the right leg which made it impossible for him to straighten the leg. Shooting pains into the hip and thence down to the ankle on the posterior aspect of the leg had been experienced from the onset. These occurred chiefly in the night when the patient was in bed and lasted from 15 to 30 minutes. Heat and counter-irritants relieved the pain at first but later had no effect. More recently heat with massage seemed to give more relief. These pains had increased in severity and frequency, particularly in the week immediately preceding admission, until they had become practically continuous at the time of admission. Excessive sweating especially along the back had appeared.

There had been an appendectomy three months previously and at this time an intraabdominal mass had been determined. A cough had continued from the time of the operation and the mucus produced was occasionally blood streaked.

To physical examination pallor was evident. A few small, discrete, firm anterior and posterior cervical lymph nodes were noted. The axillary and epitrochlear lymph nodes were barely palpable. The spleen and liver were felt. There was also marked tenderness in the course of the right great sciatic nerve. A biopsy confirmed the diagnosis of Hodgkin's disease. The course was progressively downward during the hospital stay of 63 days, during which period the patient ran a widely remittent temperature, ranging from 99 to 104.8° F.

The blood picture was particularly interesting in that a terminal level of 24 per cent hemoglobin, 1,530,000 erythrocytes, 600 leukocytes, with 53 per cent neutrophils, 1 per cent eosinophils, 45 per cent lymphocytes and 1 per cent mononuclears was obtained the day before death.

The suffering of this patient from sciatic neuritis was extreme. The clear intimation of a neoplastic background lay in the determination of an intraabdominal mass at the time of the appendectomy. Hemoptysis, remittent fever, grave anemia and profound leukopenia completed the clinical picture in this subject.

B Herpes Zoster

Case 7 A white male, aged 40, complained of a lump in the neck. He stated that twelve years previously, he first noted swelling below the right ear. A tonsillectomy was performed and there was noted further enlargement of the mass after this time. "Electric" treatments thereupon reduced the swelling. Later there appeared lymphadenopathy in the axillary and inguinal regions. Adenectomy of the right axillary nodes was performed but upon admission bilateral cervical and axillary lymphadenopathy was apparent. The previously removed nodes had been diagnosed Hodgkin's disease. During the hospital stay, sensory disturbances occurred in the flexor aspect of the right forearm with paresthesias, burning and tingling giving way to deep boring pain. Areas of vesiculation appeared in the course of the cutaneous

nerves derived from C₈, T₁, T₂, and T₃ posterior roots and a diagnosis of herpes zoster was made (Figure 2)

FIG 2 Herpes zoster complicating Hodgkin's disease (Case 7)

Case 7 presented a classical picture of herpes zoster. In our experience this is an unusual complication of Hodgkin's disease in that it has been encountered in only two other instances. Histologic sections of the involved nerves or their ganglia are lacking and it may well be argued that its occurrence is a mere coincidence. Against this objection may be cited the relatively common involvement of the peripheral nerves in the process, particularly after roentgen-therapy.

IV BONE INVOLVEMENT

Case 8 A white male, aged 34, complained of a painless growth at the angle of the left mandible for a period of three years with rather marked extension in the eight months preceding admission. A biopsy confirmed the clinical diagnosis of

Hodgkin's disease Five years and eight months following this diagnosis, after an interval treatment with roentgen-ray, the patient returned with a complaint of sharp pains at the left side of the leg, beginning three months previously and later replaced by a pain in the back that remained localized until he grew tired and then radiating in a belt-like fashion around the anterior portions of the body There had been a weight loss of 12 or 15 pounds in the preceding month, and insomnia had been quite marked The roentgenogram showed a destructive lesion in the anterior portion of the body of the seventh dorsal vertebra with marked compression and wedging (Figure 3)

FIG 3 Hodgkin's disease of the thoracic vertebra (Case 8)

Case 9 A white female, aged 23, complained of "painful glands" in the left axilla This trouble had started four years previously in the lymph nodes of the neck A year before admission the nodes in the left axilla began to enlarge These had become progressively larger in size and definitely painful Weight loss had been

pronounced and weakness progressive Two years before admission pain was noted in the right knee and right hip and the left knee and left hip had likewise become involved Seven months before admission, there was a sharp pain in the left shoulder which lasted for four days At the same time the painful nodes in the left axilla increased the degree of disability in this shoulder A weight loss of 14 pounds had occurred in the preceding three years

The physical examination showed under-nutrition, discrete enlargement of the cervical lymph nodes, similar enlargement of the nodes in the left axilla and smaller nodes in the left epitrochlear region and marked limitation of abduction of the left shoulder Roentgen-ray of the left shoulder revealed an irregular destruction of the upper end of the shaft and the neck of the left humerus with irregular thickening of the cortex and bony spicules extending out into the soft tissues (Figure 4)

FIG 4 Hodgkin's disease of the head of the left humerus (Case 9)

Biopsy of an axillary node fixed the diagnosis of Hodgkin's disease The basal metabolism was plus 35 and plus 34 The blood count showed 50 per cent hemoglobin, 5,120,000 erythrocytes, 18,000 leukocytes with 94 per cent neutrophils, 3 per cent lymphocytes, 3 per cent metamyelocytes Relief from pain attended roentgen-therapy and she continued under observation for about two years

Cases 8 and 9 are interesting examples of the destructive bone lesions of Hodgkin's disease The implications in the latter are obvious, but in Case 8 there is the added significant detail of girdle pains on the basis of radicular involvement from destruction of the body of the seventh dorsal vertebra

V VISCERAL INVOLVEMENT

A Spleen

Case 10 A white female, aged 36, complained of weakness. There was a further history of cough succeeding a cold 17 months previously. This cough was non-productive and led to a pressing pain in the midabdomen. The appetite became progressively less. Two months after the onset of symptoms, the patient became pregnant. A weight loss of 17 pounds occurred in the ensuing month. Premature delivery at seven months was followed by improvement in appetite and some weight gain. Pain of a continuous and dull order augmented by eating was noted in the epigastrium 14 months before admission and at times this pain was so severe that even the weight of a blanket was uncomfortable. Four months before admission to the hospital, the pain had become more severe and weakness was progressive.

A medical consultation led to the diagnosis of an enlarged spleen, and because of the anemia, transfusions, iron and liver were prescribed. In spite of this support the symptoms progressed without abatement.

Physical examination revealed poor nutrition, icteric pallor, wasting, an epigastric mass, splenomegaly and hepatomegaly, bilateral axillary and inguinal lymphadenopathy. The existence of pruritus was suggested by extensive excoriations. The described lymph nodes were firm, discrete, non-tender and freely movable with relation to underlying and overlying structures. Later some enlargement of the cervical nodes became apparent. The roentgenogram of the chest showed some mediastinal involvement. The basal metabolic rate was plus 38 and plus 39. A biopsy of the axillary nodes showed the characteristic changes of Hodgkin's disease.

In Case 10 the spleen was palpably enlarged but its independent responsibility for the anemia and the epigastric mass was ruled out by a detailed study with the biopsy.

B Liver

Case 11 A white male, aged 39, complained of a growth in the left groin. Five years previously he had noted a mass the size of a walnut in the left inguinal region and there had been slight but steady increase in its size. Two weeks before admission there occurred a dull ache which was particularly marked when the thigh was flexed sharply upon the abdomen.

The physical examination showed pallor of the skin, exophthalmos, palpable thyroid gland, slight hepatomegaly, splenomegaly and inguinal lymphadenopathy. The biopsy of the inguinal nodes fixed the diagnosis of Hodgkin's disease. The basal metabolism was plus 22 and plus 24. Roentgen-therapy was instituted. After a period of 40 months, the patient returned with a history of the sudden appearance of jaundice a month previously. Anorexia, nausea, vomiting and weakness attended. The stools became clay colored and the urine highly colored. No abdominal pain was noted. In two weeks, 14 pounds had been lost. Reexamination noted the jaundice with a widespread nonpruritic, papular eruption, exophthalmos, palpable thyroid gland, palpable liver, submaxillary and axillary lymphadenopathy.

An obstructive jaundice was diagnosed from the clinical course, the absence of bile in the feces and of urobilin in the urine. Roentgen-therapy was instituted and after 400 r units to the right hypochondrium in two doses the patient became definitely more uncomfortable without perceptible change in the jaundice. Four days after the discontinuance of the roentgen-therapy, bleeding from the nose, lips, gums and gastrointestinal tract was noted. The stools were bright red from continued bleeding, and the patient died the succeeding day from blood loss.

Extrahepatic biliary obstruction from lymph node pressure upon the common bile duct seemed the simplest explanation for the rapidly developing jaundice in Case 11. Upon this assumption roentgen-therapy was initiated. At necropsy, however, the major biliary ducts were found to be patent, but an extensive cellular infiltration of the liver by the Hodgkin's process had determined the jaundice. Focal hemorrhagic areas were found throughout the intestinal tract.

C Retroperitoneal lymph nodes

Case 12 A white female, aged 27, complained of pain in the right side of the abdomen. The patient had known of the existence of a lump in the right kidney region prior to hospitalization. The symptoms were those of pressure in this area. She had gained weight and suffered no other discomfort.

The physical examination showed no palpable superficial adenopathy. An irregular tumor mass approximately 6 by 8 centimeters was palpated in the right flank. Fixed and painless, this mass was believed to be either an enlarged kidney or a tumor of the kidney. The laboratory studies, including special roentgenograms, gave no clue.

This patient was interesting because of the inability to fix a preoperative diagnosis, although the consensus favored a renal tumor. An exploratory operation established a lobulated retroperitoneal mass which was excised and proved to be Hodgkin's disease.

D Mediastinum

Case 13 A white female, aged 50, complained of discomfort in the abdomen which was dated to a dental extraction six months previously. A month later dyspnea appeared when lying on the left side and asthmatic attacks of a severe order would supervene. Relief resulted on turning to the right. This change of position would regularly stop the wheezing. Shortly after this, spontaneous dyspnea appeared and she became conscious of her cardiac action. On several occasions she had a sensation of fainting and would sit down to ward off impending syncope.

Physical examinations disclosed slight exophthalmos, cervical and submaxillary lymphadenopathy and evidences of a superior mediastinal mass with a small fluid accumulation in the left pleural cavity. The fluid withdrawn from the thorax was negative for tubercle bacilli. A biopsy confirmed the diagnosis of Hodgkin's disease.

Dyspnea is a common concomitant of mediastinal Hodgkin's disease, but Case 13 showed the added postural factor in the initiation and the relief of respiratory difficulty.

E Pleura (and mediastinum)

Case 14 A white male, aged 48, complained that "it was hard to breathe." Five and one-half years previous to admission, he had felt a mass in the upper left quadrant that became painful upon movement. Weight loss and weakness had progressed and there was slight enlargement of the lymph nodes of his neck. In the next six months, these became very large and firm but they remained painless. A diagnosis of Hodgkin's disease was made and roentgen-therapy induced marked improvement. According to the patient's story his health was perfect for a period of five years, but six months before admission the mass reappeared in the upper left

quadrant and the enlargement of the glands in the neck recurred. Embarrassment of respiration developed as a result of the cervical enlargement and roentgen-therapy was initiated. Dysphagia appeared about the time of onset of the dyspnea. The physical examination was particularly significant in the confirmation of the lymph node enlargement and the establishment of enlargement of the liver and spleen. Signs of fluid were found in the right pleural cavity and 1800 c.c. of slightly blood-tinged, straw colored fluid were removed by thoracentesis. Two weeks later another thoracentesis was done and the same amount of fluid removed. The blood count showed a mild hypochromic anemia. The basal metabolism was plus 25 and plus 24 at this time. A roentgenogram of the chest showed a lobulated mass above the cardiac shadow in the superior mediastinum. Fine reticular marking was noted through both lung fields. The right lung base was clouded by homogeneous density.

After several series of roentgen-ray treatments and a progressive decline in the general condition with only mechanical advantages from therapy, the patient died 10 months after the first admission. The leukocytes reached a low level eight months before death, or three months after the first observation in the hospital, at 1,660 with 46 per cent neutrophils, 40 per cent small lymphocytes and 14 per cent large lymphocytes.

Necropsy in Case 14 showed pleural and perisplenic involvement by the Hodgkin's infiltration in addition to the accustomed changes in lymphoid tissues.

F Lung (with cavitation and superior vena caval obstruction)

Case 15 A white female, aged 32, complained of a sick feeling. Earlier observations had established the presence of a pulmonary accumulation of pus and Dr. R. H. Jackson resected two inches of the anterior arc of the right fifth rib, sutured the visceral pleura to the parietal layer and two days later aspirated three ounces of purulent material from the subjacent lung. There was some gain in strength but no improvement in the general condition. The temperature was normal for three days after returning home but the cough continued and was productive of large amounts of yellowish pus. On one occasion, six weeks before admission, considerable bright red blood was expectorated. Herpes appeared on the tip of the tongue and on the mucous membranes of the mouth three weeks before admission. Substernal soreness developed and dyspnea occurred upon coughing.

The physical examination at the time of admission was significant in the emaciation and pallor of the subject. The chest findings included marked depression above and below the clavicles, particularly on the right. The expansion was reduced at the right apex and base. The tactile fremitus was decreased to absence below the right second rib. A hyperresonant note was determined throughout the left chest, but there was dullness almost to flatness in the anterior right chest below the clavicle. Over the area medial to the right midclavicular line and above the fifth rib, amphoric breath sounds and whispered pectoriloquy were heard. Interscapular impairment was determined on the right. After eleven days of study, Dr. R. H. Jackson completed a series of exploratory punctures of the right lung under gas anesthesia. Everywhere he met with dense resistance and only occasionally could withdraw a drop of thick muco-pus.

The further course of this patient was marked by progressive decline. Twenty-three days after admission the sternum became more prominent opposite the third costochondral junction, and this prominence was reddened and very sensitive. The right supraclavicular lymph nodes became palpable at this time and the lips and nail beds quite cyanotic. Three days later a second swelling developed in the thoracic

parietes over the right fifth rib about the midclavicular line. Night sweats made their appearance and were quite debilitating. Hemoptysis recurred. Edema of the feet advanced and eventually marked edema of the face appeared. A progressive increase in the venous pressure was noted in the veins of the arms. The prominence over the sternum increased and fluctuation was elicited over the same. Eventually there was some recession of this sternal protrusion. Dilatation of the veins in the right side of the abdomen and increased resistance in the right rectus were noted. Amphoric breath sounds eventually appeared beneath the right clavicle and as low as the second right interspace. The engorgement of the veins in the neck became a prominent feature as did also the edema and cyanosis of the head, neck and arms. She finally died nine months after the first observation in the hospital. From the time of her admission until death, she ran a remittent fever ranging from normal to 104° with a downward tendency of the curve in later weeks, when the range was from 96.4° to 100°. At necropsy, extensive mediastinal Hodgkin's disease was found with invasion of the lung and definite excavation of the process in the right upper lobe. There was likewise direct invasion of the lumen of the superior vena cava by the disease and thrombosis had led to the complete occlusion of this vessel.

The patient presented a difficult problem in diagnosis until accessible lymphadenopathy appeared. Early the presence of a suppurative process in the lung seemed unequivocal. Subsequent aspirations led Dr. Jackson to believe that the pulmonary process was neoplastic. Cavitation of the lung in Hodgkin's disease is not common, but its occurrence has been reported and the signs of excavation should not militate against the diagnosis. Superior cyanosis and edema are sufficiently distinctive to make the intravital recognition of superior vena caval obstruction relatively easy.

G Lung (with expiratory *souffle voilé*)

Case 16 A white male, aged 47, first seen in the Out-Patient Department with the complaint of a progressive, painless swelling in the neck, which a biopsy demonstrated to be Hodgkin's disease. The particular interest in this patient arose from the development of unusual signs in the right base ten months later. Evidences of mediastinal involvement (history and physical examination) had existed for six weeks, when there was observed a new phenomenon at the base of the right lung. A period of silence was noted over an area medial to and below the angle of the right scapula on expiration and then a peculiar rush of air and a shower of râles succeeded by an audible cough. This phenomenon persisted for several days and then gave way to an absence of breath sounds over this area. Subsequently, a pleural friction and then signs of fluid made their appearance at this base.

Upon necropsy, three months later, among other findings, the right main bronchus showed some erosion and there was an overgrowth of the mucosa here causing partial obstruction to the right lower bronchus.

A modification of the usual *souffle voilé* is described in Case 16 in that the apparent interference with a free passage of air occurred in the expiratory rather than the inspiratory phase of respiration. A mechanical explanation for this phenomenon was established at necropsy by the changes in the right main bronchus.

VI CONSTITUTIONAL MANIFESTATIONS

A General weakness

Case 17 A white male, 59 years of age, experienced spells of weakness, a run-down feeling and nervousness about three or four months before admission. This nervousness was described as manifesting itself by a quivering of the arms and by such a shakiness of the hands that writing was impossible. Five weeks before admission he accidentally discovered a firm mass the size of a golf ball in the right axilla, which in the intervening period had increased to the size of a baseball.

The constitutional symptoms in Case 17 suggested thyrotoxicosis rather than Hodgkin's disease, but the patient was admitted for study prior to the period of routine basal metabolic determinations in the lymphadenopathies and the diagnosis was reached through a biopsy of the right axillary lymph nodes. The elevation of the basal metabolic rate in the active periods of Hodgkin's disease may at times confuse the diagnostic issue.

B Suspected focal infection

Case 18 A white female, aged 29, complained of a cough which began a year and a half before, when she began to feel listless and gradually lost weight from an average of 100 pounds to 90 pounds. Her teeth were held responsible for this decline and all teeth in the upper jaw were extracted 14 months before admission. Five days later, swelling in the nodes of the neck was observed and a cough developed which continued dry and unproductive. After a month's time, all of the teeth in the lower jaw were extracted and although there was some subjective improvement, enlargement of the cervical lymph nodes persisted. Five months after this, the symptoms of weakness had progressed markedly and a tonsillectomy was performed. In spite of the surgical procedure, the cervical nodes progressively enlarged and the dry cough continued. Five months later a biopsy was performed and the diagnosis of Hodgkin's disease made. The roentgenogram of the chest confirmed the physical evidence of a superior mediastinal invasion.

This patient had the common experience of many individuals with Hodgkin's disease, in whom an exhaustive search for a focal infectious explanation of the constitutional symptoms proves futile and the diagnosis ultimately is derived by exclusion or by an opportune biopsy.

C Suspected tuberculosis

Case 19 A white female aged 26, complained of choking in the neck. She had felt quite well until 11 months previously except for an increasing susceptibility to colds. Succeeding one of these attacks there were marked pleuritic pains in the right chest and these continued from time to time in the interval until her admission. Lack of energy was likewise noted and at the time of admission, she was beginning to have difficulty in breathing, and choking when lying on her back. The complaints had become progressively worse. Enlargement of the nodes in the neck likewise progressed but there had been some subsidence of the swelling immediately to the left of the sternum. On suspicion of tuberculosis she had been admitted to the sanatorium two months before and had been a bed patient. Constant irritating cough had occurred and there had once been a hemoptysis of one-half cup of bright red

blood. Marked night sweats, fever, dyspnea on exertion and a slight irregularity of cardiac action had been reported.

The past medical history added only the significant details of recurrent tonsillitis and "scrofula" in childhood. The family history disclosed a tuberculous background, the father having died of tuberculosis, a sister and a cousin likewise suffered from tuberculosis.

The patient was unable to lie upon her back. The hands were cool and moist and there were scars in the neck. The anterior and posterior cervical lymph nodes were enlarged. The supraclavicular nodes were particularly prominent. There was slight suprasternal bulging. The described nodes were firm and apparently discrete. There was dullness at the left apex with some impairment at the right base. The breath sounds over the left apex were quite distant. The roentgenogram of the chest showed a dense shadow in the superior mediastinum, largely obscuring the cardiac outline. A dense shadow with an irregular upper border was noted at the right base and a less extensive density at the left base. A biopsy of the cervical nodes established the diagnosis of Hodgkin's disease. A thoracentesis on the right removed 650 c c of fluid.

Case 20 A white male, aged 24, complained of pain in the chest. Indefinite gastric symptoms had existed for a year but the pain in the chest dated only five weeks past. A cough with chills and sweats was noted at the onset and there was a severe pain in the upper anterior chest, apparently beneath the sternum. Cough was of a dry unproductive type, and a remittent fever with chills and sweating appeared daily. The patient was confined to bed for two weeks and then began to move about the house occasionally. The dry cough persisted. There was pain in the chest which extended to the lower sternal region. Dyspnea appeared and he was returned to bed under the attendance of his family physician. By the fourth week, the cough became productive of mucus without blood-streaking. He was referred to a tuberculosis sanatorium but the medical director sent him to the Wisconsin General Hospital where evidences of cervical adenopathy and of a pleural effusion on the right were established. One thousand c c of fluid were removed from the right pleural cavity whereupon a coarse pleural friction became audible at the base. Bacteriologic studies and animal inoculation of this fluid showed no tubercle bacilli. The biopsy of a cervical lymph node established the diagnosis of Hodgkin's disease.

Cases 19 and 20 illustrate those frequent instances in which tuberculosis is suspected in patients suffering from Hodgkin's disease. In Case 19 the past medical and family histories clearly justified this thought. Furthermore frank hemoptysis had once occurred. Chest pains, cough, fever and sweats completed the masquerade in both cases.

D Suspected undulant fever (or tuberculosis)

Case 21 A white male, aged 35, complained of "pain around the stomach." His complaint began three months before when he experienced the feeling of oncoming gripe. Following this there was a loss of energy, and a week later coughing in the morning and evening was noted. Two weeks later the appetite was sharply reduced and there were gas pains. Weight loss became apparent and weakness supervened. After slight exertion he felt extremely exhausted and perspired profusely. A month previous to admission he again consulted a physician who told him that he was running a fever and sent him to bed. After that time, his temperature had ranged from 100° F in the morning to 102 or 103° F in the evening. He was suspected of

being tuberculous and sent to a sanatorium where he stayed for several days, but negative chest findings led to his discharge

A further confusing factor entered the story in the occurrence of undulant fever in the wife the previous summer. Her complaints had grossly paralleled the patient's. Because of the general occurrence of Bang's disease in his herd he had disposed of all cattle, cleaned his barns and procured a new herd with the exception of the few animals in the first group that had not had positive reactions. However, he had stopped boiling milk about a month prior to the onset of his symptoms.

Physical examination disclosed marked emaciation, a mass in the right axilla (which the patient thought had been present for eight years) and a small mass in the left supraclavicular fossa. There were likewise many small nodes in the right supraclavicular fossa. These described masses were non-tender, firm in consistency, and freely movable. The liver and spleen were palpably enlarged, the former extending 8 cm. below the costal margin and the latter 11 cm. The blood count on admission was 48 per cent hemoglobin, 2,050,000 erythrocytes, 4,500 leukocytes, 75 per cent neutrophils, 24 per cent lymphocytes, 1 per cent monocytes. A low level of leukocytes occurred three weeks after admission at 2,650, with 80 per cent neutrophils, 14 per cent lymphocytes and 6 per cent monocytes. A remittent fever with a range of 98 to 104° marked the hospital stay of 42 days and the patient died. Biopsy as well as necropsy findings confirmed the clinical diagnosis of Hodgkin's disease.

The constitutional symptoms had suggested the possibility of tuberculosis in this patient. The coincidence of undulant fever in his wife further confused the issue, particularly since their clinical pictures superficially tallied. The general lymphadenopathy, splenomegaly and hepatomegaly at the time of admission to the hospital simplified the problem and the biopsy clinched the diagnosis of Hodgkin's disease. The anemia and leukopenia in this patient should be especially remarked.

E Alternating pyrexia

Case 22 A white male, aged 50, complained of a fever of eight months' duration. Actually this patient had not been well since a respiratory infection 11 months before admission, but the febrile reaction began three months later. The first episode of fever lasted for five days and was attended by malaise and aching pains. Since the original attack, there had been recurrences of fever at intervals of four to eight days and the febrile episodes themselves had lasted from one to four weeks. There had been no severe shaking chills but usually the attacks were preceded by a chilly sensation of the back and the temperature ranged from 97 to 104° F. with considerable daily variation. The malaise and general aching had continued with the bout of fever. For a few nights before admission, he had regularly been delirious during the height of the fever.

The physical examination established a cervical, axillary and inguinal lymphadenopathy. The spleen was definitely enlarged. Biopsy of one of the cervical nodes confirmed the diagnosis of Hodgkin's disease. During the period of hospitalization, fever occurred at irregular intervals. The temperature ranged from 98.2 to 103.2° F. in febrile periods which lasted 13 and 14 days, respectively, and the one afebrile interval was of 12 days' duration. The patient left the hospital in a second afebrile period, which had then lasted five days.

Case 23 A white male, aged 11, gave a history of lymphadenopathy of two years' duration involving particularly the cervical region. A biopsy fixed the diagnosis of Hodgkin's disease and particular interest in this patient attaches to the febrile

course upon the fourth admission. At this time a definitely alternating pyrexia was observed with periods of remittent or continued fever ranging as high as 105° F and lasting for 11 to 18 days and afebrile periods of 7 to 15 days (Figure 5)

FIG 5 Alternating pyrexia (Case 23)

Case 24 A white male, aged 37, presented himself because of difficulty in breathing and dated his disability to an attack of pneumonia two years previously. Strength had never been regained from that time and six months before admission he experienced a respiratory infection with chills and fever as high as 103° F. During the past month there was recurrence of the fever and severe pain extending down the right leg. Paresthesias of the feet had occurred the year before. There was a history of roentgen-therapy for masses in the neck a year prior to admission. For a few days there had been a sudden impairment of hearing with headaches. Night blindness had been noted for four or five years.

Physical examination revealed a peculiar dusky pallor with unusual apprehension, restlessness and frequent twitchings of the hands and feet, widening of the palpebral fissure and slight exophthalmos, left cervical lymphadenopathy, splenomegaly and hepatomegaly. The blood count showed 58.4 per cent hemoglobin, 3,015,000 erythrocytes, 5,413 leukocytes with 83 per cent neutrophils, 0.6 per cent primitive cells, 6.8 per cent lymphocytes, 7 per cent monocytes and 2 per cent large young cells. The eyegrounds showed the characteristic changes of retinitis pigmentosa.

The most significant detail in this patient's clinical course was the continued fever ranging from 103 to 104.8° F for nine days and then followed by lysis over a six day period to normal. Temperature was maintained at this level for the remaining ten days of the first hospital stay. When he was readmitted 22 days later, another bout of fever was encountered, ranging from 102 to 105° F until his death three weeks later. His blood count six days before death was 57 per cent hemoglobin, 2,770,000 erythrocytes, 8,800 leukocytes with 94 per cent neutrophils, 5 per cent lymphocytes and 1 per cent monocytes.

The term, alternating pyrexia, was suggested by Gowers¹⁴ and it is accurately descriptive. At the same time it avoids the controversial issue of priority in the definition of the remarkable bouts of fever interrupted by afebrile seasons in this disease. An erroneous impression should be corrected. While the alternating pyrexia has definite diagnostic value in Hodgkin's disease, it is the least common type of febrile reaction to this condition. Remittent fever is much more common and continued fever is not unusual. As stated before, a fixed regularity in the form and the duration of the phases of alternating pyrexia of Hodgkin's disease may be predicted at times. As a rule the fever is remittent in such bouts. In these details Case 22 falls close to the rule, but Cases 23 and 24 are exceptions. Case 23

ian the alternating pyrexia as a terminal picture and Case 24 had recurrent bouts of continued fever of striking constancy. In any event the diagnostic significance of alternating pyrexia in the presence of even suggestive evidence of Hodgkin's disease should not be overlooked.

VII BLOOD

A Anemia

Case 25 A white male, aged 39, complained of shortness of breath. The present condition was initiated five months previously by pain in his arms extending to his finger tips and a sensation of numbness in the latter. The pain was usually aching and occasionally accompanied by similar discomfort in the legs. "Fatigue aches" the patient termed them. Shortness of breath had progressed and dizziness was observed in the morning on rising. There had been a sore mouth two years previously, relieved by repair of the teeth. Soreness of the tongue over the past year had responded to brushing of the teeth with soda. Extreme night sweats had appeared over the past three months and there had been chills with sweats. Palpitation and dyspnea had advanced steadily as had also the paresthesias.

The physical examination included a yellow pallor, palpable liver and spleen. A few inconspicuous inguinal and epitrochlear nodes were noted.

The laboratory examinations included the blood count: 40 per cent hemoglobin, 1,170,000 erythrocytes, 2,900 leukocytes without a significant differential change. The gastric analysis showed no free hydrochloric acid, even after the injection of histamine. The icterus index was 8. Urobilin in excess was found in the urine. The basal metabolic rate was plus 30 and plus 29. A diagnosis of pernicious anemia was made. Concentrated liver extract administered parenterally at five-day intervals effected no improvement in the general condition. Because of the poor condition of the patient and the failure of response to liver, a transfusion was done 15 days after admission. A continued observation of the marrow insufficiency, anemia, leukopenia and thrombocytopenia, attracted attention and it was furthermore significant that the improvement from transfusions was not maintained. Finally, 88 days after admission, a small lymph node in the left posterior cervical chain was noted, a biopsy obtained and the diagnosis of Hodgkin's disease made. Whereupon roentgen-therapy was initiated and the earlier advantage of transfusions became very much more pronounced in the improvement of the blood picture. A month later the following level pertained: hemoglobin 70 per cent, erythrocytes 5,140,000, leukocytes 6,850.

The erroneous diagnosis of pernicious anemia in this patient was not discovered until the failure of response to adequate liver therapy led to a search for an explanation. The hypochromic anemia, pigment changes and achlorhydria all added to the confusion. The palpable spleen should have aroused suspicion, but only upon failure of specific therapy was a lymph node excised and the diagnosis of Hodgkin's disease made. The response of the blood picture to transfusions after roentgen-therapy was as spectacular as the subjective improvement.

B Leukocyte formula in prognosis

Case 26 A white female, aged 41, complained of weakness. Eighteen months previously she had suffered from a sharp rheumatic pain in the right arm, radiating from the shoulder to the elbow and aggravated by motion. This pain continued in

severe intensity for a month and then disappeared to return with cold weather and hard work. For several months before admission the pain had persisted and the patient noted firm lumps in either side of the neck. With effort, as in doing the family washing, the right arm would swell, become blue and paresthesias would occur without actual pain.

The physical examination determined the presence of a pyramid of discrete, non-tender lymph nodes in the cervical region with the base at the angle of the jaw. The largest nodes were in the upper end of the chain. Axillary lymphadenopathy and inguinal involvement were evident to physical examination, and mediastinal involvement to roentgen-ray. Upon repeated examinations during the succeeding nine months, the blood count ranged from the initial level of 65 per cent hemoglobin, 6,590,000 erythrocytes, 23,200 leukocytes, 88.2 per cent neutrophils, 1 per cent eosinophils, 6.6 per cent lymphocytes, 4.2 per cent monocytes, to a level of 40 per cent hemoglobin, 3,260,000 erythrocytes, 31,800 leukocytes, 96 per cent neutrophils, 2 per cent lymphocytes and 2 per cent monocytes twelve days before death.

From Bunting's work^{9,10} the leukocyte formula in Hodgkin's disease assumes an exceedingly important place in the prognosis. Clearly the isolated numerical leukocyte count means little in any condition and in this disease a single differential picture avails nothing, but by repeated determinations in skilled hands it is possible in conjunction with the clinical findings to trace the stages and to predict the outcome of this disease with a measure of assurance. The patient passes from a stage of lymphoid resistance with an inversion of the formula to that of lymphoid paralysis when in a terminal period the neutrophils may number as high as 98.5 per cent of a grossly elevated leukocyte count.

C Suspected leukemia

Case 27 A white male, aged 39, complained of distress after meals. Until three years previously he had been entirely sound and then suffered from neuritis and a "tired feeling." Tonsillectomy was performed and the patient was much relieved for six months, whereupon early fatigue returned. For 10 months night sweats appeared practically every night. Eight months thereafter thyroidectomy was performed with some temporary improvement. Two months prior to admission he began to lose ground again. Sweats returned nightly and there was considerable distress after meals. A sense of pressure developed half way through the meals and remained two or three hours thereafter. This feeling of distress appeared after every meal. There was a 10 pound weight loss before admission.

The physical examination revealed a sallow complexion and red beefy tongue with prominent fungiform papillae. Marked enlargement of the liver and spleen and free fluid in the abdomen were noted. A few supraclavicular nodes were palpated. The blood count on admission showed 55 per cent hemoglobin, 3,690,000 erythrocytes, 58,000 leukocytes, 92.75 per cent neutrophils, 0.25 per cent eosinophils, 4.5 per cent lymphocytes and 2.5 per cent metamyelocytes. Basal metabolism was plus 32 and plus 35. A high point in the leukocytes was reached 13 days after admission at 71,000, 91 per cent of which were neutrophils.

A diagnosis of chronic myelocytic leukemia was maintained for some time until the persistence of the above leukocytic formula, remittent fever, lymphadenopathy and the clinical course necessitated a review of the im-

pression and the consideration of Hodgkin's disease. A biopsy confirmed this diagnosis.

D Leukopenia

Case 28 A white male, aged 35, complained of swelling of the "glands" in his neck, which dated back three months and was first noted as a part of a general lymphadenopathy. After a period of roentgen-therapy in the hospital, he was treated as an outpatient on two occasions over the next six months. An interval of eight months elapsed before a readmission, at which time he reported an interval of freedom of symptoms and of regained weight and strength during the summer of the previous year. With the return of cold weather the lymphadenopathy had recurred and there was pain in the left lower quadrant. Weakness and fatigue marked the subjective picture at this time. There was general lymphadenopathy and hepatomegaly. A further series of deep roentgen-therapy was administered at this time. The patient returned to the hospital four months later with a history of further fatigue and bleeding of the gums. After a rest period of a month, he returned obviously in a sharp relapse with marked pallor, marked exophthalmos, enlarged liver and spleen and general lymphadenopathy. The interesting change in the advancing anemia and leukopenia reached an extreme point in the latter detail with 450 leukocytes, 35 per cent neutrophils and 65 per cent lymphocytes, three days before death. At this time the hemoglobin was 45 per cent and the erythrocytes 2,490,000.

Naturally the contribution of roentgen-therapy to the profound leukopenia in Case 28 must be seriously considered. In our judgment it was an important factor in this instance, but the natural occurrence of a grave leukopenia has in several other patients led to a suspicion of an aleukemic leukemia and the necessity for a marrow biopsy where accessible lymph nodes were not enlarged. Boyer's recent review of leukopenia in Hodgkin's disease¹⁵ is very illuminating.

VIII CONCURRENT TUBERCULOSIS AND HODGKIN'S DISEASE

Case 29 A white male, aged 48, gave the history of axillary lymphadenopathy of seven years' duration, succeeding a felon on a finger of the left hand. Removal of a lymph node from the left axilla ten months after the onset led to a diagnosis of Hodgkin's disease. After a further interval of eight months more nodes reappeared in the left axilla and grew to the size of a grapefruit. Roentgen-therapy led to some subsidence, but there was later enlargement of nodes in the right axilla and also in the cervical region. Further roentgen-therapy was applied but the nodes had recurrently appeared in intervals between the treatment.

Upon physical examination the nodes in the cervical region were small, discrete and non-tender. Similar nodes were defined in the inguinal region. The nodes in the axilla, however, were slightly tender, confluent and adherent. The biopsy was illuminating in that the coexistence of tuberculosis and Hodgkin's disease was established.

Case 29 merely substantiates Ewing's statement, "Tuberculosis follows Hodgkin's disease like a shadow"¹⁶

This brief review of the experience in one clinic emphasizes the necessity for diagnostic awareness of the possibility of Hodgkin's disease in a

number of guises. Clearly the clinical pattern must not be too sharply drawn or many cases will escape early recognition. The constitutional and hematopoietic reactions of the disease appear to be especially susceptible of misinterpretation unless the diagnostic consciousness of these possibilities be ever present at the bedside. Finally the laboratory aids to the diagnosis should be regularly invoked. The blood picture, in expert hands, has certain diagnostic features, but even disregarding this somewhat controversial issue, invaluable prognostic information may be gathered from the routine study of the differential formulae of the leukocytes upon frequently repeated studies through the course of the disease. Basal metabolic studies give unequivocal evidence of the activity of the process, but no diagnostic inferences may be drawn from the same. The biopsy of accessible lymph nodes frequently fixes the diagnosis and even upon suspicion should be regularly employed in this relation.

THE INTERNIST AND THE SYPHILIS CONTROL PROGRAM

By HUGH J. MORGAN, M.D., F.A.C.P., *Nashville, Tennessee*

AMONG the objectives of the American College of Physicians that have been enumerated in the articles of its Constitution are "maintaining and advancing the highest possible standards in medical education and medical practice, maintaining both the dignity and efficiency of internal medicine in its relationship to public welfare, to foster measures for the prevention of disease and for improving public health." If the College is to maintain these purposes and ideals, the fullest participation on the part of the membership is required in the current program for the control of syphilis, for this is the major public health effort of this decade.

The first paper in the first number of the first volume of the ANNALS OF MEDICINE (the precursor of our ANNALS OF INTERNAL MEDICINE) contains the following statement: "The exponent of internal medicine must know syphilis in all of its manifestations and its results. For its widespread incidence must always be taken into account as modifying disease or dominating therapy throughout the whole field of internal medicine." Thus did the president of the American College of Physicians in 1920, Dr. Reynold Webb Wilcox, in an address defining the range and scope of internal medicine, lay claim to the disease, syphilis, as rightly belonging in the domain of the internist. I suspect that Dr. Wilcox was moved to make these remarks because of the neglect of the disease by his colleagues and because he had witnessed the tendency on the part of urologists and dermatologists to seclude it in the field of their activities. His remarks may have been intended to constitute protest. However this may be, I am sure we can agree that it was then and is now a most desirable thing that medical men exhibit a keen interest in this infection. Lay and professional concern regarding syphilis is mounting steadily. It is therefore, proper that the internist look critically at the problem as it affects his practice and the public health, admitting, insisting upon, a share in the responsibility for preventing, diagnosing, treating and, when possible, curing this malady.

Those most interested in the syphilis control program expect much of the members of this College. It is felt that the position of the internist in his community is such that he will be peculiarly effective in encouraging professional and lay education, in engendering an enlightened, aggressive attitude toward the syphilis problem, in stripping it of prejudices and taboos in order that scientific medicine may better realize its possibilities. Are internists really in a position to play so important a rôle in the program? An affirmative answer is inescapable. The internist's training is such that

* Read at the St. Louis meeting of the American College of Physicians, April 21, 1937.

he understands the significance of the term "generalized infection" and is cognizant of understood and obscure factors which operate in infectious disease. The patient and, alas, often the urologist and dermatologist may be seriously concerned in acute syphilis only with a genital ulcer or an exanthematous eruption. The internist recognizes that long before these lesions have made their appearance, the virus of syphilis is widespread throughout the body. Of tremendous importance from the standpoint of spread of disease and, therefore of the public health, the superficial early lesions have no more clinical significance in the patient's health than the localized, granulomatous ulcer marking the site of entrance of *B. tularensis* in tularemia or the rose spots scattered on the skin of the abdomen in typhoid fever. The internist knows from sad experience that the immediate threat of acute syphilis is not directed against the patient's health but against his or her contacts (the public health),—that the ultimate threat is against the cardiovascular and central nervous systems. Because he is familiar with chronic disease the internist can appreciate the significance of the term "latent syphilis" with its sinister implication that latency may be followed by activity. Furthermore the disciplines which the internist has experienced render him respectful of learning and eager for guidance when the latter is authoritative and based on scientific study and accomplishment. Data dealing with the relative value of various methods of diagnosing and treating syphilis have been accumulated. Now one can say that there are proper and improper methods. Facts have supplanted opinions regarding many treatment problems. There is irrefutable evidence that these facts are not being utilized by the majority of physicians treating syphilis. The internist appreciates the gravity of the implications of this statement, for he encounters the results of poor treatment in patients with cardiovascular, central nervous system and congenital syphilis. It is high time that he interest himself not so much with discouraging studies relative to this or that method of treating syphilitic aortitis, syphilitic hepatic cirrhosis, tabes and paresis, but with the application of his knowledge and skill to the prevention of these often irreversible, lethal conditions. This he can do if he will accept as his own the problems of preventing and treating acute and latent syphilis.

Is it worthwhile? Is syphilis so important after all? "The high incidence of known cases seeking treatment, the ratio of early syphilitic patients under treatment to the exposed contacts infected (for two individuals with early syphilis who seek treatment there are three exposed contacts infected) and the accumulating number of untreated or inadequately treated individuals with syphilis are the basis for the estimate that one out of ten adults in the United States today has or has had syphilis"¹ "A half million people acquire syphilis each year in the United States or one and one half times as many as acquire tuberculosis"²

It is estimated that there are at least 25,000 fetal deaths from syphilis

in the United States each year - It is believed that 40,000 deaths from cardiovascular syphilis occur annually. Vonderlehr has estimated that each death represents a loss of from 19 to 23 years of life with the result that the total loss from cardiovascular syphilis is from 800,000 to 850,000 years of life annually. There is a minimum of 4,500 deaths per year from paresis and 1,100 from tabes. "Since each death from paresis represents a loss of about 22 years of life and each death from tabes a loss of about 14 years of life," Vonderlehr estimates that the total loss from these two conditions is about 100,000 years of life annually in the United States. Thus it is seen that the United States population loses well over 900,000 years of life annually from cardiovascular syphilis, tabes, and paresis. The cost of the disease is apparent in terms of morbidity and mortality. The cost in dollars and cents to taxpayers, philanthropic boards, and private patients for institutionalizing for many years the physical derelicts of the disease is formidable. I shall not attempt a consideration of it. Suffice it to say that the cost is obviously far greater than for any plan for control, however expensive the latter may be.

Is it feasible to attack the problem? What weapons have we, and are they effective? The etiology of the disease is known. We have accurate tests for its presence. The diagnosis, in cases which can be effectively treated with present methods, is not difficult. Treatment, though far from ideal, is effective, if properly applied, in (a) curing and rendering non-infectious the vast majority of patients with early syphilis, (b) in preventing congenital syphilis, (c) in protecting patients with latent syphilis from the sequelae of chronic infection, and (d) in prolonging life and comfort in the established, chronic disease. If our present knowledge were utilized to its fullest, the disease could be promptly brought under control. To this end, a program, sponsored by the United States Public Health Service under the leadership of Surgeon-General Thomas Parran, has been formulated. This program involves education of profession and public as to both the menace of the disease and the possibilities of its control, the improvement of facilities for the care of patients of all economic groups, the development of a public health attitude toward the disease with special emphasis on case finding through contact studies, rendering patients with acute syphilis non-infectious by proper treatment, curing, when possible, and preventing congenital syphilis. To this end the practitioners of the country, who care for over half of the syphilis which is recognized and under treatment,³ and the public health forces are being organized for the attack. Is it not fitting that we consider and establish our position, as internists, in this undertaking?

The first and most effective thing that the individual internist can do to contribute to the success of this control program is to familiarize himself with modern concepts of diagnosis and management of the disease—to learn and practice sound medicine in so far as syphilis is concerned. No more important step could be taken toward the successful consummation of this

program than that the internists of the country give syphilis its proper place in their discussions, thought and practice. How many internists are actually mindful of the following facts relative to syphilis: that it is a generalized infectious disease long before the appearance of skin and mucous membrane lesions, that the acute stage of the disease is a critical period in the life of any syphilitic from the viewpoint of the public health since it is the time that he or she infects others, that the early acute phase of the infection is the time during which the spirochetes are disseminated throughout the body, and that it is the time of the laying of foundations for the later development of cardiovascular and central nervous system disease, and, finally, that the acute disease is clinically curable.

Are these important facts known to all internists and, if they are, are all internists duly impressed with the great opportunity for prevention and cure that each patient with acute syphilis presents? Is it common knowledge that the present standardized methods of treatment for acute syphilis, involving scheduled treatments for well over a year, are greatly superior to other treatment plans and that the patient's chance for cure is dependent upon such management? ¹ Do all good physicians use these methods? Does every patient with acute syphilis raise a question in the doctor's mind as to the existence of unrecognized contact infection? Does he try to find the source of his patient's disease and render it non-infectious? Does he think of syphilis and its threat whenever he sees a pregnant woman and does he insist upon a serological test for its presence or absence? The answer to most of these questions is in the negative. The medical profession in general, including internists, must admit to an attitude of casualness and indifference with regard to syphilis, which is, to say the least, inconsistent with medical traditions and ideals.

What, to be specific, should the intelligent internist know and do? What are the "minimum requirements" with regard to attitudes and practice?

First, know and teach that syphilis is highly infectious during its acute phase and that for every case of acute syphilis there is a source and that this source spreads disease.

Second, know and teach that the foundations for serious, late manifestations of syphilis are laid in the early stage of the infection.

Third, know that the acute stage is the important stage to treat—both from the public health point of view and also from the point of view of the patient's future health. Here is the golden opportunity to practice both preventive and curative medicine.

Fourth, remember that even after the golden opportunity has passed, congenital syphilis can be prevented and many of the sequelae of syphilis can be forestalled by adequately treating latent or chronic syphilis.

We shall see in this generation a marked reduction in the incidence of acute syphilis in the United States. Many of us will live long enough to witness a reduction in the incidence of congenital syphilis, neuro-syphilis,

cardiovascular and visceral syphilis. Bereft of its age-old prejudices and taboos the syphilis problem is being presented to the medical profession and to the public. Means to cope with and to solve this problem are at hand. They are admittedly not ideal but they are, nevertheless, effective. Failure of the current program could be attributed only to lack of intelligent co-operation on the part of all parties involved—a most important group being, for reasons which I have indicated, the internists.

PROGNOSIS IN TUBERCULOSIS¹

By F M POTTENGER, M D , F A C P , *Monrovia, California*

INTRODUCTORY

WHEN one considers the prognosis of tuberculosis in its widest implications he is obliged to extend his discussion to every phase of the tuberculosis problem and consider every factor which influences bacillary growth and activity or modifies individual resistance. The outcome of the disease is influenced by the virulence and numbers of infecting bacilli, the type of the disease and its severity, the constitutional peculiarities of the patient, his general reacting powers, his condition at the time when infection occurs, the character of the tissues which are involved, the nature of the lesion, the time when the diagnosis is made, the character of treatment and when it is instituted, the age, economic and social status and intelligence of the patient, the character of the climate and weather to which the patient is exposed, the psychology of the patient and of the friends who advise him, the physician who carries out the treatment, his psychology as well as medical knowledge and experience in meeting the problems of the tuberculous patient, the place where the treatment is to be carried out whether at home, in a sanatorium or in a dispensary, and many other factors of greater or lesser import.

It is not always the big thing that determines the outcome in tuberculosis. We at times see the prognosis changed from favorable to unfavorable and the reverse as a result of some very small factor which might, under ordinary conditions, seem of minor importance.

In the time allotted to this paper I shall confine myself largely to the influence which a competent physiologic reaction and a competent compensating mechanism on the part of the patient has upon the prognosis of tuberculosis, and further point out the difference in a prognosis from the standpoint of healing and from the standpoint of physical efficiency.

TWO BASIC FACTORS ON WHICH PROGNOSIS DEPENDS

The healing of tuberculosis is a physiologic process, and, when the physiologic balance of the patient is good, tuberculosis shows a strong tendency to heal. That the prognosis is favorable, provided the disease is treated intelligently in its early stages, is now generally acknowledged, because the patient's resisting power is good and the ability of the lung tissue and thoracic cage to compensate for the loss which results from infiltration cavity or fibrosis is excellent. When these early cases fail to heal it is usually due to the fact that conditions necessary to the healing process were

* Read at the St. Louis meeting of the American College of Physicians, April 20, 1937

not established. That the prognosis is less favorable in the far advanced stages and when improperly treated in all stages is equally well established.

With the well established forms of treatment everywhere recognized today, there are few places in civilized countries where a patient suffering from tuberculosis can not be given a fair chance of recovery if aid is sought at a time when the disease is curable. This is very different from what it was a quarter of a century ago, for even so recently as that, well trained specialists were few, the general opinion of physicians was that the disease was hopeless, and the aid necessary to cure was rarely to be had.

The two most potent factors in changing the prognosis of tuberculosis in recent years from the status of an all time hopeless disease to that of one that is curable have been the large group of medical men who have made tuberculosis their special study, and the systematic spread of knowledge concerning the nature of the disease by interested workers. It is almost an unbelievable fact that this change in prognosis has come within a single generation.

NEXT STEP IN IMPROVING PROGNOSIS

Probably the next greatest advance in prognosis will be brought about by the medical profession considering tuberculosis in the same category as other diseases. General medical men should understand tuberculosis and show the same interest in it that they show toward diseases of the heart, kidney and gastrointestinal tract, or diabetes or blood diseases. When they do this we may hope not only for an earlier recognition than today, but also for the application of treatment when it will be more effective. In no disease can a physician render a greater service to a patient or to his family than in making an early diagnosis of tuberculosis and directing him so that he at once receives adequate treatment and at once minimizes the danger of infecting others. It not only means saving the patient's life and restoring him to usefulness, but saving others who associate with him from infection. The importance of instituting immediate treatment is particularly emphasized by the fact that the disease so often affects the bread-winner and is so often found in the years of early adult life when the domestic, economic, social and cultural interests of the family depend upon the patient's ability to carry on with as little loss of time and efficiency as possible.

PROGNOSIS AS IT RELATES TO IMMUNOLOGIC REACTION

In order to make an intelligent prognosis we must understand something of the intimate reactions which make up the defense mechanism of the patient, for these are basic in prognosis. They vary greatly in different individuals. Tuberculosis is a chronic inflammatory disease. The accompanying inflammation is due to the reaction between bacilli and their products on the one hand, and the tissues of the patient on the other. The reaction, being inflammatory, carries with it local irritation of cells, dilata-

tion of blood vessels, and an exudation in the tissue spaces with an increased serum and cellular content at the site of the injury, all of which belongs to the defense reaction.

Both bacilli and tissue cells may be destroyed as a result of the conflict which goes on for mastery. As a result of the irritation and destruction of tissue cells, enzymes are set free which produce bacteriolysis. Destruction of bacilli is further carried on by cells which possess phagocytic qualities. Resulting both from the growth and the destruction of bacilli, substances are set free into the tissues which gain access to the circulation and stimulate the defensive function of cells throughout the body. Thereafter, when bacilli or bacillary substances gain entrance to the tissues they are anchored and destroyed with increased avidity.

Local defense takes upon itself two forms, one that of bacteriolysis, the other that of tubercle formation, the one primarily destructive of bacilli, the other primarily fixative in that it tends to hold them in situ.

General defense, on the other hand, consists in establishing an increased power on the part of the tissues generally for opposing both bacilli and bacillary products. While certain cells normally have greater defensive powers than others, it seems that every cell of the body is endowed with the function of defense and that it is stimulated to unusual proportions as a result of infection. We call this increased defense immunity. This increased physiologic reaction is the factor which makes it possible for the organism to oppose successfully millions of bacilli in advanced extensive tuberculosis, although first infection may have been brought about by a very few.

While the defense strategy of the body, in case of an attack of microorganisms, consists in concentrating its most effective forces at the point of invasion it carries out the principle of universal conscription and arms all cells so as to guard every area of the body from attack while continuously sending up new forces to the front so as always to have fresh troops guarding the most exposed areas.

In order to understand how prognosis may be modified by the general condition of the patient it is necessary to understand that specific defense is a quickened and heightened response of a physiologic function normally possessed by the body cells, and, that this function is just as normal as that which produces secretions having special properties or that which produces muscular action. So, warding off infection, destruction of invading microorganisms, and the repair of the injury which has been caused are all physiologic processes, the competency of which depends much upon the condition of the patient.

The body's defense is sufficient as a rule to either wholly destroy the few bacilli which enter the tissues at the time of first invasion, or, to hold them largely fixed at the point of entry and in the lymph glands which drain the infected area. But the fact that infection is established is evidence that the numbers of bacilli are greater than the local cells, with their normal

protective function, are able to cope with, and, furthermore, it is evidence that unless this protective power can be increased the infection cannot be successfully opposed. The general principle in physiology of increased response to unusual stimulation now quickly comes into play, and within a few days after bacilli have become implanted in the tissues all cells of the body are able to put up an augmented defense. If tuberculosis extends thereafter, it does so against increased opposition which tends to restrict the extent and severity of the metastases. The prognosis in the more simple lesions which succeed the primary complex is determined very largely by the degree of competency of this protective mechanism.

Tuberculous infection, opposed by increased cellular defense, results in the so-called "adult type of infection." In the adult type, on account of this increased cellular defense, the lymphatic route of spread which was open and free to bacilli at the time of first infection is now largely closed, shutting off the easiest route for bacilli to follow in spreading throughout the body. Bacilli which enter the tissues by way of the blood and canalicular routes such as the bronchi now also meet with increased opposition to implantation and are often destroyed without producing infection, or, if infection is established, it often becomes abortive. This protection in the previously infected individual is so efficient that, unless the numbers of infecting bacilli be great, there is little danger of permanent metastases forming in the early stages of the disease provided, of course, the patient is put at bed rest and so treated as to maintain a normal physiologic response. The increased local and general physiologic responses of the body, if only the patient is maintained in a state of high physical fitness, make the prognosis in early clinical tuberculosis almost invariably favorable.

PROGNOSTIC SIGNIFICANCE OF CASEATION

While the major pathologic processes may be described as predominantly exudative and predominantly proliferative, the most serious phenomenon which is met in the pathology of tuberculosis, the one which carries with it the possibility of affecting prognosis most unfavorably, is caseation and softening, because this process is responsible for cavity formation and furnishes the source of bacilli which produce metastases by spreading through such natural channels as the bronchi.

A patient may be incapacitated by the gradual encroachment which a preponderantly proliferative lesion makes upon his reserve pulmonary tissue, but sooner or later caseation with destruction of tissue and cavity formation will usually accompany and increase such incapacity. It is caused by a violent protective reaction of immunized tissues against an unusual number of infecting bacilli or large quantities of their protein products. Multiple cavity can be largely prevented by the immediate application of adequate treatment while the disease is early.

Caseation often takes place early in exudative infections because the tis-

sues are in a state of hyperergy. The anchoring ability of the cells is so great that the protein is fixed in such large quantities that it obstructs the capillaries, cuts off the blood supply to the tissues, and causes them to caseate and undergo destruction, but as the tissues become more accustomed to the infection it seems that the degree of protection becomes greater while the cellular reaction becomes less violent. This is of great prognostic significance, for either a degree of desensitization of the cells takes place or the protein is prevented in some other manner from producing severe localized reactions. While cavity often accompanies an early exudative lesion, a second one rarely follows immediately thereafter, even though the infection continues to spread, and furthermore, few relatively large cavities appear during the course of chronic proliferative lesions except as a result of the fusion of smaller ones. This highly protective mechanism can be relied upon as being the greatest factor in the healing of tuberculosis. Even the extent of destruction may be kept to a minimum by taking advantage of it by the modern methods of treatment which limit the danger of metastases forming by keeping the patient in a state of high physiologic balance. This may be accomplished by the application of rest and other proper physiologic therapeutic measures immediately on the infection assuming clinical importance.

Even a large cavity, today, is far from being the hopeless phenomenon that we formerly thought. The early freshly formed cavity, unless it be situated unfavorably, will usually heal spontaneously, if the patient's reacting powers are quickly brought to a state of efficient action, for the pulmonary tissues are able at this time to take on emphysematous change, and the bony thorax is able to reduce in size and lessen its movement, and these together bring about the conditions required for healing. However, unless cavity is treated properly, it reacts very unfavorably upon prognosis, for it reduces the chances of healing and furnishes an open focus from which bacilli can readily spread and form other metastases.

PROGNOSIS IMPROVED BY ARTIFICIAL COMPENSATORY MEASURES

Up to the present time most patients who have been treated for tuberculosis have been treated after the disease has become advanced. In these cases both the physiologic balance of the patient is severely disturbed and the mechanism by which compensation takes place between the lung volume and thoracic cage has already been utilized to its limit. So physicians have spent their energy attempting to overcome the many discouraging conditions which this chronic infection presents. However, they have been unwilling to accept defeat and by their ingenuity have devised measures with which to cope with many of the mechanical conditions which adversely influence the prognosis in these cases. The physiologic factor, too, is gradually becoming better understood, but there still is no way of restoring the function of exhausted cells. In healing tuberculosis, nature lessens respiratory move-

ment and reduces the size of the thoracic cage to adjust to the volume of pulmonary tissues as it is reduced by the disease. The tissues adjoining infiltrations in the lung also adjust by becoming emphysematous and enlarging, thus relaxing and compressing the infiltrated and excavated tissues.

Experience has shown that these results may be attained artificially by utilizing relaxing and compressing measures, such as weights upon the chest wall, pneumothorax, pneumoperitoneum, paralysis of the diaphragm and thoracoplasty. These measures promote healing mechanically by reducing respiratory movement, relieving diseased pulmonary tissues of tension, and compressing them. In many cases of advanced tuberculosis these measures bring about favorable mechanical conditions without which a physiologic balance, no matter how stable, would be unable to produce healing. However, no matter how frequently healing follows, it must be understood that the protective and reparative processes depend upon the patient's physiologic response.

PROGNOSIS FOR HEALING AND EFFICIENCY DIFFERS

Through relaxing and compressing measures the prognosis in many cases of severe and serious tuberculosis has now become fairly favorable from the standpoint of bringing the disease to a state of quiescence or arrest. This is truly a great accomplishment, but it is still unsatisfactory in that it too often restores a mechanism, which has been injured by neglect, to a limited capacity when our knowledge and understanding of the problems involved warrant a restoration to full capacity. Any measure that carries with it an avoidable reduction in the patient's future efficiency, no matter if the tuberculous process is healed, has in it elements of defeat which medicine must overcome.

To make my meaning clear it is only necessary to contrast the health and full efficiency which a patient suffering from an early limited lesion usually secures through treatment, with the handicap of limited efficiency and insecurity which he usually obtains through the most effective treatment possible when the lesion is far advanced. When we see the interference with the mechanics of respiration, the reduction in lung volume, and the resultant inability to compensate and measure up to the calls for extra physical exertion which is a common occurrence following the best result that can be attained in many far advanced cases of tuberculosis, we should be led to bend every energy towards securing treatment at a stage when such handicaps would rarely follow.

DISCUSSION

From the preceding discussion it may be established that in combating tuberculous infection and in promoting healing we are dealing with functions with which the patient is normally endowed. If cure is accomplished, the patient accomplishes it through these normal functions. If we, as physi-

cians, improve the prognosis, we do it by increasing the patient's own powers and facilities, not by adding something new and extraneous. If only we bear in mind that the phenomena which we meet in the tuberculous process, the proliferation, the exudation and the necrosis, are intimately connected with the immunologic and healing processes, which in turn depend upon the physiologic mechanism of the patient, we will be able to make a more accurate prognosis.

In regard to prognosis it can be said that with stable physiologic equilibrium and favorable conditions for compensatory adjustment on the part of an individual, a limited infection produced by a relatively large number of bacilli, or a smaller number of relatively virulent bacilli, may readily heal, and an infection which may occur at a time when the host's physiologic equilibrium is temporarily lowered may be healed by restoring his physiologic processes to normal, but, should an infection be large or the bacilli be extra virulent, or should the host's physiologic processes remain in a condition of instability for too long a time, then healing of the process may not only fail to take place but metastases may form creating other foci of infection, and from these further metastases may take place, repeating the cycle until healing may become impossible.

While mildly reacting limited lesions are comparatively easy to overcome, multiple or extensive lesions produce a proportionately greater disturbance in the host's physiologic and compensatory processes and bring about a relatively greater tax on his defensive and healing powers. So an advanced and advancing process reduces the favorableness of prognosis by presenting greater difficulties to be overcome before healing may be accomplished, and by causing the host's protective and healing mechanism to be rendered less effective for its task. It is self-evident, then, that the favorableness of prognosis steadily decreases as the tuberculous infection extends quantitatively and as the pathologic changes advance in severity. It is likewise self-evident that a rapid restoration of the patient's physiologic functions, among which is that of defense against infection, greatly improves the prognosis in any case.

Theoretically, one should have little fear but that a normal physiologic function on the part of an individual with a limited tuberculous infection would be able to bring about healing provided it is maintained long enough, and this has been proved by many years of experience. Theoretically, one should expect that the more advanced the process quantitatively and qualitatively the greater the difficulty in securing a healing and the less efficient the patient would be thereafter, and, the experience of many years has shown this to be true. Theoretically, advanced tuberculosis with destructive lesions should be difficult and often impossible to heal by any possible restoration of physiologic balance, and many years of experience have also shown this to be true.

The prognosis in tuberculosis is modified by the character of the lesion,

which depends very much upon the individual patient and his particular physiologic reaction. It furthermore is plain that these two factors are largely in the hands of the physician, to be modified through the application of therapeutic measures. Whether the disease will spread or the patient will be able to defend himself successfully against it depends very much upon the treatment which is carried out. Since healing is primarily physiologic this places the burden of prognosis largely upon the physician, for he determines whether or not a proper physiologic balance is established and maintained.

Before the necessity of maintaining an equilibrium between the size of the thoracic space and the lung volume was understood as being a prime factor in prognosis, pneumothorax and other measures of relaxing and compressing the pulmonary tissues were established, and it was thought that their main purpose was compression or enforced rest to the lung. While this is often true in far advanced cases, it is hardly so in those early cases which will heal spontaneously under hygienic measures alone. Compensation in these cases is necessary rather than active compression.

It is generally accepted that pneumothorax has improved prognosis more than any other measure used in treatment. There is no doubt that it reduces the danger of spreading, that it improves the chances of certain advanced cases that were found to be incurable by older methods, and that it gives the physician a control over the patient. It will not only produce favorable results in a very large group of comparatively early cases, but also in another group that rarely heals without some form of artificial aid. This, particularly, is what has made it so popular, for most cases under treatment belong to this class. However, let us not deceive ourselves, for the best prognosis, with or without compression, is found in early cases.

If we were to discuss the manner in which prognosis is influenced by various procedures, we should divide the patients into those in whom artificial compression measures are necessary and those in whom they are not. As it is now, credit is given to compression measures in many instances in which the lesions would have probably healed under hygienic measures alone. Those early cases in which the patient is able to make his own compensation, if collapsed, add to the prestige of pneumothorax, when in reality a similar result could have been obtained without it.

Pneumothorax has become exceedingly popular in instances in which adequate medical supervision cannot be had. The great majority of tuberculous patients are treated in public institutions in which the number of beds is inadequate and the medical service is undermanned. Therefore, it has become necessary to meet the problems with the facilities which are at hand. To do this compression therapy has been used, not so much because it is necessary for healing, but as a matter of expediency in order to make the facilities meet the needs of the community. Early cases in which the question of healing under hygienic measures is hardly questioned are submitted to

compression therapy, the purpose of which is to render patients bacillus-free as quickly as possible and send them back to their homes, leaving the beds in the institution for others

All of the early cases that are collapsed in this way add to the prestige of collapse therapy. The effect is to brand the prognosis in most cases of tuberculosis as unfavorable unless collapse therapy is used. That such an attitude is wrong may be shown by the statistics of institutions which treated tuberculosis before artificial compression was generally used. How wrong it is cannot be determined until statistics covering many cases treated with and without pneumothorax are analyzed in an unbiased manner. Recent studies from English sanatoria show better results without operative measures while those from Detroit show best results with

Admitting that artificial compression, particularly pneumothorax, will enable us to secure a healing in many patients in whom we would fail otherwise, let us not forget that rest with spontaneous compensation or spontaneous compensation supplemented by temporary phrenic interruption will bring about healing in a very large percentage of the early cases and restore the patient to health with a minimum degree of physical inefficiency, produced either by the disease or as a result of the therapy. Pneumothorax produces injury to the respiratory mechanism of the patient in quite a number of instances, and in discussing prognosis all such injuries must be considered. Thoracoplasty, which is a boon to the patient who faces the alternative of healing with incapacity of one lung or of remaining ill, cannot be defended as a desirable treatment. It is the treatment that all would like to escape if possible, but the years of life and comfort it adds are a blessing to the one who cannot do better. We hope, however, that its necessity will become less and less as the truths about tuberculosis become more generally disseminated.

Tuberculosis specialists should urge early diagnosis and immediate restoration of physiologic balance as one of the most important factors in improving the prognosis of this disease. No one would take from far advanced cases the opportunity of healing, even though they are seriously handicapped during the rest of their lives, but the fact that these patients with advanced disease can be handled successfully from the standpoint of cure must not blind one to the unnecessary loss of efficiency that is brought about by treating cases which are far advanced instead of early.

The improvement in prognosis which has been brought about by scientific ingenuity should be accepted for what has been accomplished, but it should not satisfy medical men if better results are possible. On the contrary, it should stimulate humanitarian sentiments so that every tuberculosis worker would proclaim long and loud, in season and out of season, that lives and efficiency are needlessly sacrificed by allowing clinical tuberculosis to extend beyond the time when its cure can be brought about in most instances through the stimulation of normal physiologic functions and through na-

ture's own compensatory mechanism, 'or at most by the use of the simpler operative measures

SUMMARY

The cure of tuberculosis is accomplished through normal physiologic processes. The lung may be reduced in volume by infiltration, cavity and fibrosis, and the adjustment of lung volume to the size of the thoracic cage is important in healing. In advanced cases healing may be prevented unless such compensation can be made. The prognosis, then, depends upon physiologic competency and compensatory adjustment.

The prognosis for healing and for efficiency differs. The prognosis in tuberculosis in its early stages is favorable for healing, and also for the future efficiency of the patient. The prognosis in far advanced cases, with the newer methods of treatment, is quite favorable for healing, but the prognosis for efficiency is lowered.

The profession should not be satisfied with the present status of therapy. Too many patients come under treatment only when the lesions are of such severity that the measures required to produce healing are so radical as to entail a lamentable reduction in the patients' future respiratory efficiency.

In order that patients may be treated during the favorable stage of the disease, the medical profession should take the same interest in tuberculosis as it does in other diseases, prepare itself for making early diagnoses and understand the principles of therapy, so that proper treatment may be immediately applied.

SCARLET FEVER¹

By JEAN V COOKE, M D , *St Louis, Missouri*

THE modern conception of scarlet fever may be summarized briefly as follows

The evidence that scarlet fever is caused by hemolytic streptococcus infection is convincing and this etiology of the disease is generally accepted as proved. The constant association of the clinical disease with some focus infected with these organisms, the production of experimental scarlet fever by purposeful inoculation of susceptible volunteers with cultures of streptococci, and the various biologic reactions produced by injection of hemolytic streptococcus filtrates leave little room for doubt that the hemolytic streptococcus is the essential cause of the disease. As a result of observations on scarlet fever as a streptococcus infection, it has become evident that the disease is a composite one and that the manifestations can be separated into two distinct groups. The first group includes those phenomena resulting directly from infection and invasion of the tissues by the streptococcus and constitutes the *septic* component of scarlet fever. These septic manifestations are clinically identical with those of similar nonscarlatinal pyogenic infection and include the acute pharyngitis of varying degree seen in the usual form of scarlatina, as well as the localized infection of the skin or endometrium noted in the surgical or puerperal types, the direct extension of the infection to adjacent tissues in such complications as otitis, mastoiditis, cervical adenitis, or phlegmonous angina, and the accompanying malaise, fever, and leukocytosis common to acute streptococcus infections of this character. The second or *toxic* component of scarlet fever includes those added manifestations which are caused by the absorption of specific toxic substances derived from the streptococci themselves. All of these can be reproduced in susceptible persons by the injection of sterile streptococcus filtrate and are obviously quite distinct from the changes produced by direct tissue invasion by the organisms. The purely toxic phenomena include the rash with the accompanying enanthem, the initial vomiting, slight general adenopathy, fever, and, in addition, the less constant manifestations of arthritis and hematuria. Although the toxic phase is combined with the septic in clinical scarlet fever, the two processes are immunologically separate. Certain persons, for example, who are immune to the toxic action of absorbed bacterial substances, may suffer severely from scarlatinal streptococcus infection—the *scarlatina sine exanthemate*—and in many fatal cases of the disease death occurs from the septic infection after the specific toxic symptoms have disap-

¹ Presented at the St. Louis meeting of the American College of Physicians, April 21, 1937.

From the Department of Pediatrics, Washington University School of Medicine, and the St. Louis Children's Hospital.

peared. Conversely, it has been noted not infrequently that certain children with marked skin sensitivity to the streptococcus filtrate fail to develop scarlet fever after exposure. This again shows the lack of a constant relationship between susceptibility to the toxic phenomena and immunity to streptococcus infection. Those persons, for example, whose cells are very susceptible to the action of streptococcus products, may possess a well-defined tissue immunity to streptococcus infection. Such protection from scarlet fever is probably dependent on local tissue resistance to infection rather than on circulating antibodies.

The relative seriousness of the effects of these two distinct components of scarlet fever is of some interest. In general the septic element of the infection is by far the more important part of the disease. All serious and fatal complications which are observed appear directly attributable to the invasion and extension of the streptococcus infection. While the specific toxic symptoms are clinically more striking and obvious, they are of relatively short duration, in the majority of cases of a mild character, and have usually disappeared by the time any serious septic complications occur. Those very rare fulminating cases in which severe toxic symptoms are followed shortly by death have suggested that the fatal outcome could be directly attributed to the specific scarlatinal toxemia, although even in such instances death might as readily be due to the intense streptococcus inflammation.

While the exact part played by the specific toxic phase in the serious effects of scarlet fever is as yet unsettled, it is difficult to believe that it plays any but a minor rôle. Regarding the infection itself, the conditions upon which individual resistance or susceptibility to the entrance of the infecting streptococci depends and the manner by which the body overcomes the infection are very imperfectly understood and the recent investigations on scarlet fever have furnished no explanation of them. Whether the specific scarlatinal toxemia has any part in making the septic streptococcus infection more serious is still uncertain. Certainly such added specific toxemia produces a more intense clinical illness during the first week of the infection, although in general the complications and sequelae of streptococcal infections without a rash appear to be quite comparable in degree and severity with similar infections of scarlatina with typical toxic rash.

In the past 50 years the morbidity of scarlet fever has apparently increased while the mortality has decreased. The most probable explanation of this is that during this period there has been an increasing percentage of very mild infections. Whether such infections are actually acquiring a less virulent character, or whether many patients now diagnosed as scarlet fever were previously called nonscarlatinal toxic rashes it is impossible to determine, but possibly both factors play a part in the increased morbidity and decreased mortality. In recent years the mortality has varied from 0.5 per cent to 3 per cent, and the normal mortality is considered to be around 2 per cent. As with all streptococcus infections, especially when they occur in epi-

demio form, there are some years in which virulence and mortality are somewhat above the normal rate. It is important to remember such periodical variations in the virulence of epidemics, especially in interpreting the results of therapy, since certain claims for specific therapeutic measures are based on mortality variations well within normal yearly variations. To the laity the term "scarlet fever" still carries a menace to life and hearing not at all justified by the character of the disease as it exists today.

The question of the relationship of so-called nonscarlatinal streptococcus infections or those without the specific skin rash to typical clinical scarlet fever is an interesting one. It is generally accepted that when scarlet fever occurs in epidemic form, certain contacts suffering from typical streptococcus throat infections but with no rash or other specific toxic manifestations, actually have scarlet fever infection without a rash. On the other hand, when similar streptococcus throat infections occur sporadically, they are usually called merely acute tonsillitis and few consider a possible relationship between them and scarlet fever. Epidemiologically, however, the physician who treats scarlet fever finds that the majority of the patients he sees are sporadic cases and have not been in contact with another case of the disease. It has often been puzzling to understand how such a large percentage of patients with a communicable disease could acquire it without apparent exposure. It has, therefore, become increasingly evident from a purely clinical standpoint that streptococci capable of producing scarlet fever are very widely distributed. The problem of the specificity of streptococci causing scarlet fever, therefore, becomes of some importance epidemiologically, and the question of whether a certain strain of streptococcus or several strains, or indeed almost any pathogenic hemolytic streptococcus may cause scarlet fever, must be considered. The classification of these organisms and their identification and separation has been studied by two methods. First, by means of such bacteriological methods as agglutination and agglutination absorption experiments with immune serums, and second, by a comparison of their ability to produce a specific skin reactive toxin, or specific erythrogenic substance which is neutralizable by human or animal immune serums. Several workers have shown, for example, by agglutination tests with immune rabbit serums, that a very large proportion of the strains isolated from scarlet fever had similar agglutinative characteristics and could be differentiated from strains isolated from nonscarlatinal sources, such as local or general pyogenic infections. This strongly suggested that certain strains were specific for scarlet fever. On the other hand it was later shown that the streptococci isolated from early scarlet fever cases not only differed from those from other sources but also differed from those streptococci isolated from patients with scarlet fever during the third and fourth week of convalescence. Such differences suggest that the group relationships demonstrable by agglutination tests may be altered by the environmental factors in the host which change the specific agglutinability of the streptococci, and that

these differences may not be due to inherent strain differences. Eagles, for example, believes that hemolytic streptococci are a group of organisms whose specific agglutinative qualities may be altered by factors operating upon them in vivo. There is much evidence for the belief that with streptococcus infections just as with tubercle bacillus infections, the different types of clinical disease produced may depend not on variations in the strain or type of infecting organism, but on differences in the host himself. While age, portal of entry, dosage and virulence of the infecting agent are of some importance, the varying reactivities of host's tissues, such as cellular resistance, constitution, and especially previous contact with the infecting antigen, must have a large effect on the type, character and severity of the clinical manifestations.

The second method by which attempts to demonstrate specificity have been made, has been the study of the ability of any given organism to produce a scarlatinal toxin, or the specific erythrogenic substance in culture filtrates. Most streptococci isolated from scarlet fever produce such toxin, although there is a considerable variation in the amount of toxin formed by different strains. Streptococci from nonscarlatinal sources, such as middle ear and mastoid infections in infants or other suppurative lesions, and even erysipelas also produce scarlatinal toxin in a large percentage of cases, and different organisms show a similar variation in titer of toxin. Occasionally strains from nonscarlatinal sources are far more potent in producing it than scarlatinal strains. This toxin from nonscarlatinal sources cannot be distinguished from scarlet fever toxin, since it is neutralized by scarlatinal antitoxin and immunization of Dick positive children by it is followed by the development of negative Dick tests to scarlatinal toxin. As further evidence of the similarity between the toxin produced by streptococci of scarlatinal and of nonscarlatinal origin may be mentioned the effect of various types of streptococcus anti-serums on acute scarlet fever. Many if not all varieties of commercial anti-streptococcus immune serums, such as anti-erysipelas serum and polyvalent anti-streptococcus serum, have the same effect in causing a fairly prompt fading of the rash and other toxic symptoms when administered early in scarlet fever, as does the scarlatinal antitoxin made from strains of scarlatinal origin. It is possible, for example, to produce a Schultz-Charlton local extinction test or local blanching of an early scarlatinal rash by the intradermal injection of 0.001 c.c. of certain commercial anti-erysipelas serums. Since such serums are produced from strains other than those from scarlet fever, it seems evident that nonscarlatinal strains contain the so-called specific erythrogenic toxin with considerable frequency.

From such observations as have been briefly summarized it would seem that there is little evidence that scarlet fever streptococci possess a specificity that distinguishes them from other streptococci, that the potentialities of any streptococcus to cause scarlet fever must depend largely upon its ability to produce the erythrogenic toxin to which patients with clinical scarlet fever are susceptible, that a large percentage of streptococci from scarlatinal and

nonscarlatinal sources can form this toxin, although there is some variation in the amount produced, and, finally, that if all strains of streptococci cannot secrete toxin in sufficient amount to cause the toxic symptoms in susceptible persons after infection, certainly the dissemination of streptococci capable of producing the clinical disease is so widespread that one may well consider any open streptococcus infection as a potential source of scarlet fever. In general, if the infection occurs in a person immune to the toxin because of the presence of specific antibody in his blood, the diagnosis is non-scarlatinal streptococcus disease, whereas if it occurs in a person susceptible to the toxin, the disease is called scarlet fever.

The inconsistencies of this attitude are apparent and there is an increasing tendency among many to doubt whether scarlet fever is to be any longer considered as a distinct disease entity. It seems likely that clinical scarlet fever is merely a toxic syndrome that accompanies hemolytic streptococcus infections in certain susceptible persons and it would be more consistent to consider it a scarlatinal type of streptococcus infection or a streptococcus infection with scarlatinal toxic reaction.

It has been mentioned that in the majority of cases of scarlet fever infection, the specific toxic symptoms are mild and no attempt at specific therapy appears warranted. In certain patients the toxicity is severe and in these, the injection of serum antitoxin produces a fairly prompt and often striking beneficial effect on the rash and other toxic symptoms. Such an effect, however, is obtained only if the serum is given in the first three days after the rash appears, and if serum is administered later when the toxic symptoms have reached their height, no beneficial results are observed. Serum treatment, even though given early, appears to have little or no effect upon the septic manifestations or on the streptococcus local infection. Frequently patients have been observed in whom early serum treatment produced a prompt and apparently complete cure of the specific toxic phenomena, but later the septic streptococcus disease spread alarmingly and in certain instances was fatal. Indeed as previously cited, practically all dangerous manifestations are attributable to the septic component of the disease and occur or persist after the specific toxemic symptoms have disappeared. The chief function of serum treatment appears to be symptomatic and directed primarily at controlling the toxic symptoms. When these symptoms are mild, the use of serum is not indicated. A striking disadvantage of routine use of serum in such mild cases is the frequency with which various types of serum reactions occur, some of them causing considerably more distress than the scarlet fever itself. There is little evidence that serum treatment affects the ultimate outcome of the infection.

Although it would appear that the specific toxic factor and the specific toxemia play a far less important and serious part in scarlet fever than the septic streptococcus infection, the character of the toxemia and the mechanism of its production are of much interest. There are two main hypotheses

which have been advanced to explain the production of scarlatinal toxemia. These hypotheses are quite different and a belief in one or the other of them alters considerably one's conception of the mechanism of scarlet fever, and one's procedure in attempting to control it. They may be termed the *toxin hypothesis* which assumes that the toxic agent is a primary streptococcus bacterial exotoxin analogous to other such familiar toxins, and the *allergic hypothesis* which asserts that the streptococcus product producing the symptoms is not primarily toxic and that its toxic action is due to an acquired hypersensitivity of the host's cells from previous streptococcus infection. Before speaking of the evidence supporting these hypotheses, these two types of poisons may be briefly defined so that the distinction between them may be more apparent. A true toxin is a substance which poisons or injures normal cells unless such cells are protected by the presence of a specific neutralizing antibody or antitoxin, which is a cellular product resulting from previous contact with the same toxin. An allergen, on the other hand, has no poisonous action on normal cells unless such cells do have a specific antibody which is a product resulting from previous contact with the same allergen or antigen. With a true toxin the specific antibody, therefore, protects the cells from toxic injury, while with an allergen the specific antibody renders the cells susceptible to toxic injury.

The chief observations upon which the toxin hypothesis is based are as follows:

- 1 The production of characteristic toxic symptoms by the injection of the filtrate into susceptible persons.

- 2 The appearance of a local area of erythema (Dick reaction) in the skin of susceptible persons after the intradermal injection of filtrate.

- 3 The presence of a neutralizing antibody in the blood of convalescent scarlet fever patients, of many persons with negative Dick reactions, and also of filtrate-immunized animals. This antibody resembles an antitoxin since (a) when the toxic filtrate is mixed with serum containing the antibody, the filtrate will no longer produce a positive Dick reaction on the skin of a susceptible person, (b) when the serum is injected intradermally in an early scarlet fever rash, a local blanching of the eruption occurs after a few hours, and (c) intramuscular injection of serum in early scarlet fever cases frequently causes a relatively prompt disappearance of the specific toxic symptoms.

- 4 By the injection of filtrate into persons with positive Dick reactions, using small quantities at first, followed by gradually increasing doses, the Dick reaction becomes negative, and after some weeks the specific neutralizing antibody appears in the blood.

It is apparent from the foregoing characteristics that, under certain conditions, the filtrate is toxic for man and that it stimulates the production of neutralizing antibody. In these respects, the analogy to a true bacterial exotoxin is close. However, in certain other respects the biologic reactions

and properties of the filtrate differ considerably from known soluble toxins. For example, the specific toxicity of the filtrate is limited to human beings, and in animals no toxic symptoms are produced by its injection, in spite of the fact that animal blood contains no neutralizing antibody. Young infants, also, show no toxic effect from the filtrate and have negative skin tests, even though they are unprotected by the specific antibody. Apparently, susceptibility to the filtrate is limited to human beings and acquired after infancy. In addition, the filtrate itself is considerably more stable than a true toxin since its potency is relatively unaffected by heating and by age. These and other discrepancies between the action and properties of scarlatinal streptococcus filtrate and true toxins make it less certain that the former is a primarily toxic substance and suggest the possibility that the toxic effect of the filtrate in man might depend on an acquired allergic hypersensitivity.

According to the allergic hypothesis there exists an unsensitized state at birth but the streptococcus infections during early life and the absorption of specific antigenic substances produced by streptococci incite the production of specific antibody with a resulting cellular hypersensitivity. A later infection by the same organism, if accompanied by rapid antigen absorption, produces a generalized hypersensitivity reaction evidenced by the toxic syndrome of scarlet fever. This reaction desensitizes the patient by the removal of the specific antibody. Sensitized persons may, however, develop streptococcus infection characterized by slow antigen or allergen absorption, and under such circumstances the desensitization is accomplished gradually without production of a generalized scarlet fever reaction. The allergic hypothesis, however, assumes the possibility of another state with regard to the anti-scarlatinal antibody, that is, an anti-anaphylactic state characterized by the presence of a great excess of circulating antibody, which can combine with absorbed allergen in the circulation, and therefore prevent its reaching the sensitized cells. Clinical allergic reactions occur, apparently only when the antigen combines with antibody in the cells, and when antigen combines with free antibody in the circulation no clinical toxic reaction occurs. After an individual, as a result of excessive or continued absorption of the scarlatinal allergen, has developed a large amount of the antibody in the blood, he shows no clinical scarlatinal reaction to later streptococcus infection. It will be seen, therefore, that the allergic state of an individual with regard to the scarlatinal streptococcus allergen at any given time depends upon the amount and location of the specific antibody present. At birth he has none, and, therefore, there is no cellular skin sensitivity to the antigen (as shown by a negative Dick test), and there is no antibody demonstrable in the blood. When, as a result of later streptococcus infections the cells develop specific antibody in them, their sensitivity is shown by the development of a positive skin Dick test but still no circulating antibody is present. It is in this state of sensitivity that a streptococcus infection may be accompanied by the

scarlet fever syndrome, after which the skin cells are desensitized, the Dick test is negative, but there is still no circulating antibody. Indeed—and this is probably one of the most significant observations that favor the allergic theory—not only during the period of the rash, but after the rash and other toxic symptoms have disappeared, the erythrogenic antigen or toxin can be demonstrated in the patient's circulating blood, that is to say, the patient's blood serum produces positive Dick tests on susceptible or sensitive persons. Such an observation of antigen in the circulation after desensitization could be expected in the case of an allergen, but the presence of a true toxin in the blood after recovery from the specific toxemia would appear difficult to understand.

After desensitization, the absorbed antigen again stimulates the formation of specific antibody and sensitization returns, but when antibody is produced in excess by the cells, it appears in the circulation and the individual becomes anti-anaphylactic. In this state, he is immune to the allergic manifestations of antigen-antibody reaction, because when a subsequent streptococcus infection leads to further absorption of antigen, it is neutralized in the circulation and does not reach the sensitive cells. The amount of circulating antibody varies from time to time as recurring streptococcus infection increases its titer, or freedom from the infection leads to its gradual disappearance from the blood, and the consequent unmasking of the cellular sensitivity. The general reaction with rash and other toxic symptoms of scarlet fever occurs only in those persons who develop a hemolytic streptococcus infection with rapid antigen absorption when in this state of cellular sensitivity. During the early progress of the general reaction in scarlet fever, further combination of antigen with intracellular antibody can be suddenly halted by neutralizing the circulating antigen by the injection of an excess of free antibody thereby creating a state of transferred anti-anaphylaxis.

One final comment may be made on the two hypotheses. Whichever one comes ultimately to be accepted as the true explanation of the scarlet fever symptoms, each of them can be regarded as somewhat unique. If the streptococcus product is a true toxin, it is quite different from other such toxins, chiefly in its relatively weak toxic action and the fact that its activity seems limited to human beings. On the other hand, if the agent is an allergen, the presence of a specific neutralizing or inhibiting antibody and the hypothetical anti-anaphylactic state finds no analogy in other human allergic reactions.

The allergic hypothesis, however, is supported by a wealth of immunologic analogy, and has the merit of offering an adequate explanation for the various clinical phenomena observed in connection with hemolytic streptococcus infections, skin sensitivity tests, and scarlet fever.

THE PRODUCTION OF EXTRASYSTOLES BY MEANS OF THE CENTRAL NERVOUS SYSTEM

By C. KORTH, M.D., Berlin, Germany

THE occurrence of centrally inaugurated heterotopic impulses in the human heart was first reported by Lucke. Auricular extrasystoles were observed in a 54 year old man in association with a skull injury and severe *commotio cerebri*. A year after the injury the disturbance in rhythm had become even more marked, with the occurrence of fairly long series of successive extrasystoles. A second patient, aged 50, was observed, who for about seven years had suffered a compulsion polyuria resembling diabetes insipidus together with a slight fever which exhibited normal diurnal temperature variations. These findings required for their explanation the assumption of a lesion in the midbrain. The condition persisted for several years, after which cardiac symptoms developed, and ventricular extrasystoles were found in the electrocardiogram. No heart disease could be demonstrated. Lucke assumed a central production of the extrasystoles in both cases. In the first case, a *commotio cerebri* and in the second, a lesion in the midbrain had presumably led to a reaction in the region of the parasympathetic nucleus.

Lucke cited as the only previously known phenomenon of similar nature the case described by Kulbs of a 16 year old boy who developed a marked bradycardia following a severe emotional upset. The electrocardiogram showed a sinus bradycardia with flattening of the P-wave and ventricular automatism. This observation, however, is of no particular interest in connection with our present concern, the central origin of extrasystoles. Even though we do not believe that the sharp distinction made by Wenckebach and Winterberg between active and passive heterotopy is in complete accord with the multiple possibilities of origin of extrasystoles, still, the occurrence of a compensatory rhythm in a very slow sinus frequency presents a condition which can be termed a normal behavior of the heart, purely passive in origin. In this paper, however, we are considering the more or less "active" heterotopies in the sense of Lewis' "heterogenetic" contractions, that is, true extrasystoles. We are concerned less with the strict classification of extrasystoles or their sharp distinction from parasystoles, for example, than with as fundamental an understanding as possible of the conditions of origin of heterotopy in the individual case. It must be emphasized that responsibility for the origin of clinically observed extrasystoles can never be attributed solely to a single cause. The occurrence of an extra-

* Received for publication June 23, 1937

From the 1st Medical Clinic of the Charité, Berlin (Prof. R. Siebeck, Director)

systole is bound up with a definite situation originally created by the combined effect of many single conditions. From such a standpoint, and in view of the experimental results shortly to be described, it seems to us that in both cases reported by Lucke, the assumption of a central stimulatory effect as the initial cause of the extrasystoles is very likely valid.

If we assume the central origin of heterotopic stimulus formation in the heart, then the only pathway for the transmission of the stimulus that can be considered is that of the long cardiac nerves, particularly the vagus. Until recently the difficulty of such a conception lay perforce in the fact that no action of the vagus on the ventricles of the mammalian heart could be demonstrated. Direct vagus action is unlikely according to the most recent investigations as well. However, Scherf's very searching studies of the origin of extrasystoles show that there certainly exists an indirect vagus effect upon stimulus formation by tertiary centers. He was able to demonstrate a paradoxical effect on mammalian hearts poisoned with aconitin. Along with the normal blocking effect on the sinus node, there occurred ventricular extrasystoles. This indirect vagus effect is apparently to be explained by the arrival of the vagus affecting substance from the auricles to the ventricles, at the circulatory pathway, where it influences the damaged, peculiarly sensitive tertiary centers in paradoxical fashion. Engelhart found a much smaller content of vagus substances in the ventricles than in the auricles of the mammalian heart. Scherf found in this fact supporting evidence for his conception of the manner in which the vagus affects the formation of stimuli in the ventricle. To be sure, this still fails to explain why the vagus affecting substance, which has been brought to the ventricles by the circulatory pathway, does not have an inotropic effect as well (Rothberger and Scherf).

The reflex origin of extrasystoles has been recognized for a long time. Levy, in particular, was able to generate extrasystoles in this way in cats under chloroform narcosis by means of stimulation of the accelerans. Schott reported heterotopic stimulus formation in poisoned hearts as a result of clamping off the carotids. Schott has collected the extensive literature dealing with cardiac arrhythmias of reflex origin. Among clinical observations in this connection, only the findings of Lennox, Graves and Levine need be mentioned here. These authors found extrasystoles in 70 per cent of patients on a surgical service during operations on the head or neck, whereas during operations on other parts of the body extrasystoles were observed in only 40 per cent of the patients. They concluded from this that vagus stimulation was responsible for the increased occurrence of arrhythmias during operations on the neck.

Beyond the mere idea that the extracardiac nerves are effective in the development of extrasystoles, it has recently been possible actually to produce extrasystoles by central stimulation. Brow, Long and Beattie were able to produce extrasystoles by stimulation of the central vagus stump in cats.

which had been narcotized by means of chloroform, and they further succeeded in causing cessation of the extrasystoles by means of a properly directed incision in the hypothalamic region. This "extrasystole center" must of necessity have lain above the "Sherington level." Dikshit took up the experiments of Brow, Long and Beattie, and investigated the effect of substances injected into the ventricles of the brain on the production of extrasystoles. In this way heterotopic stimulus formation was inaugurated by means of the injection of acetylcholine into the lateral ventricle or into the third ventricle in the cat. Since both vagi were cut, transmission of the stimulus via the sympathetic was assumed. Caffeine and nicotine were found to have a quite similar effect. In several different experiments, no elevation of blood pressure, which may in itself cause extrasystoles, was observed. It was further possible to demonstrate the central origin of the extrasystoles, in that it was consistently possible to cause the extrasystoles to disappear very promptly by means of the intravenous or intraventricular injection of barbital. Dikshit further assumes that the stimulating substances exercise their effect on hypothalamic centers.

The effect of strophanthin when injected into the ventricles of the brain in dogs was investigated by Korth, Marx and Weinstein. The animals were trephined in a preliminary operation and it was possible to conduct the actual experiments without narcosis. This was important because in this way the observations could be carried out on the completely intact heart without previous sensitization. It was apparent that the strophanthin had exercised an extremely strong central stimulatory effect. The electrocardiographic tracings regularly showed a constant and very characteristic picture: a few minutes after the injection there developed first a sinus tachycardia, soon ventricular extrasystoles appeared, which quickly became preponderant and finally led to a true ventricular tachycardia with a rate of about 300 per minute. Thus, strophanthin, when given intraventricularly, causes a violent heterotopic formation of stimuli in tertiary centers. By means of intravenous administration of barbital, it was possible at once to cut short the ventricular tachycardia. Since the tachycardia could be maintained even after section of the vagus, it may be said that the transmission of stimuli is possible by way of both the sympathetic and the vagus. It is very difficult or indeed impossible, to distinguish between a vagal and a sympathetic effect (Wirkweise). (Scherf has pointed out the problems involved in the investigation of vagal and sympathetic effect on the origin of extrasystoles.) In addition to the above experiment, the effect of other highly active substances (histamine, acetylcholine, thyroxin, etc.) was investigated. It was found that the effect of strophanthin was distinctly different from that of the other substances tried. It may be mentioned here that, as a result of the experiments of Korth, Marx and Weinberg, there must be ascribed to strophanthin a specific effect in increasing cardiac activity by way of the central nervous system. The recognition of this fact would seem to be important for the understanding of the therapeutic effect of digitalis.

In consideration of all these facts, we are able to say that the possibility of the origin of ventricular extrasystoles on the basis of a stimulation of nerve centers in the brain has been experimentally demonstrated. The vegetative nervous system is primarily to be considered as the transmitting organ of the central stimulus.

We wish to report herewith a clinical observation on a patient with softening of the left cerebellar hemisphere, which furthers the hypothesis of a central nervous origin of ventricular extrasystoles.

CASE REPORT

A 58 year old coal dealer, J. G., came under our care March 8, 1937 with the following history. Three weeks previously he had suddenly been taken ill while doing gymnastic exercises. He felt a "tearing sensation" in the region of his heart. Immediately thereafter there were mild pressing sensations in the precordial region which, however disappeared after a few days. Nevertheless, shortness of breath developed on mild physical exertion, often accompanied by sweating and vomiting. Further, dyspnea, though less severe, also occurred during the night so that the patient had to sit up for a few minutes. Ten days before his entrance to the clinic his physician had diagnosed a mild cardiac weakness and advised treatment in the clinic.

The patient gave a history of severe diphtheria in childhood. He had had diphtheria again as a soldier at the age of 20, for which he was kept in the hospital for five weeks. Nothing was known of any other previous illnesses.

The examination showed enlargement of the heart, especially to the left, confirmed roentgenologically. On fluoroscopy the left auricle also appeared enlarged and small calcifications could be demonstrated in the mitral valve. The heart sounds were faint and no murmurs could be definitely heard. The pulse was absolutely irregular and the electrocardiogram showed auricular fibrillation. There was no edema, the liver was not swollen and percussion and auscultation of the lungs were negative. A diagnosis of mitral disease was made. Under strict dietary treatment the patient had a marked diuresis. He received verodigen from March 13 to March 20, corresponding to a total dosage of 2 grams of digitalis leaves. He felt distinctly better and was allowed to be up out of bed occasionally. The blood Wassermann reaction was negative. The systolic blood pressure varied between 110 and 125. On March 21, which was the fourteenth day of his illness, in the morning he suddenly complained of violent dizziness. He was found lying in bed, groaning and covered with a cold sweat. The patient was completely conscious and remained so. He said that after his bath he suddenly felt very sick, after which there was a sudden attack of severe vertigo so that he was able to reach his bed only with difficulty.

The examination showed the following findings. The color of the patient's face changed frequently and suddenly. marked redness with plainly perceptible warmth of the skin was followed by equally abrupt pallor. At short intervals beads of cold sweat appeared on his forehead and cheeks. The fingers of both hands occasionally showed a cyanotic bluish color and felt cold. He could not sit up in bed. A few minutes later it was observed that the left half of his face drooped. The folds of the face on the left side were smoothed out in comparison with the right. In addition, the patient complained of recurrent attacks of nausea. However, he did not vomit. The blood pressure remained unaltered. The tendon reflexes in his arms and legs were diminished, but equally strong on both sides, and pyramidal tract signs were not demonstrable. The pupils reacted normally to light and convergence. There was no nystagmus. There was no dysphagia.

Particularly striking was a noticeable irregularity of the pulse. While even the day before his pulse had been almost regular, even with the continuing auricular fibrillation, now suddenly numerous, or indeed showers of extrasystoles could be heard over the heart. The size of the heart was unchanged on percussion. The patient was given atropine 0.001 gm subcutaneously. About $\frac{1}{2}$ hour after the injection and an hour after the onset of the grave clinical picture the pulse again became more regular. The following day no extrasystoles could be noted. On the next day the patient failed noticeably. The marked vasomotor phenomena had ceased, to be sure, and only the vertigo persisted, and to a lesser degree than before. The patient died on the evening of March 22.

The autopsy revealed an embolus at the origin of the basilar artery and acute pale softening of the left cerebellar hemisphere. The mitral valve was markedly stenosed as the result of an old endocarditis, with scarring of the external papillary muscle. The left auricle was markedly dilated and hypertrophied. It could be assumed, accordingly, that the embolus in the cerebral artery had its origin in the left auricle.

In figure 1 we have placed together several different electrocardiographic tracings of this patient. The first tracing represents the electrocardiogram

FIG 1

Top tracing March 19, before the attack
 Middle tracing March 21, $\frac{1}{2}$ hour after the attack
 Lower tracing March 22, the day after the attack

of March 19, the day before the apoplectic insult. Auricular fibrillation is apparent. The effect of the digitalis medication is seen in the reduction of the ventricular rate to about 60 per minute. The interval cannot be definitely determined because of the fibrillary arrhythmia. The second tracing is from the electrocardiogram of March 21, about one-half hour after the onset of the attack. Numerous ventricular extrasystoles, which occur in approximate alternation with normal beats, are apparent. In no instance do two normally conducted ventricular beats follow one another, giving the picture of bigeminy. The rate of the conducted beats shows no essential change from that of the preceding day. At least, no demonstrable tachycardia has developed. A rather long interval between an extrasystole and the next normally transmitted ventricular beat is evident. In the bottom

tracing we have finally the electrocardiogram of March 22. The extrasystoles have completely disappeared. The ventricular rate has meanwhile risen to approximately 140.

Thus in this case, in the course of an apoplectic insult affecting the left cerebellum, there suddenly developed showers of extrasystoles. The unusually marked vasomotor phenomena with simultaneous facial paralysis give rise to the presumption that medullary centers were sympathetically involved by the acute softening. We were unable to find any simpler and more obvious explanation of the extrasystoles than the supposition of a stimulating effect on the bulbar vagal center. In favor of this is also the fact that the extrasystoles were easily suppressible by means of atropine. We particularly wish to emphasize that the patient was fully conscious both during the insult and later, that the blood pressure remained unchanged and that there were no signs of circulatory failure.

It is further important to an understanding of these extrasystoles to note that the patient had received a total of 1.9 gm. of digitalis during the days preceding the onset of the insult. Just as in the case of the experimental extrasystoles produced reflexly by the cardiac nerves, previous intoxication of the heart was necessary, so in our case the digitalis treatment provided the necessary "sensitization" of the heart muscle. In the presence of an already existent readiness for heterotopic stimulus formation, the vagal stimulus resulting from the insult led to this manifestation of the heterotopy. Our observation presents a clear analogy to the paradoxical effect of a vagal stimulus on the formation of stimuli in the heart poisoned by aconitin as observed by Scherf. Even though the normal stimulus-inhibitory effect of the vagus on the sinus node is not demonstrable in our patient because of the auricular fibrillation, nevertheless we may assume a negative dromotropic effect of the vagal stimulus on the atrioventricular stimulus conduction. To be sure, it must be noted in this connection that the digitalization had already in any case led to a clearly evident retardation of ventricular activity, but during the insult the rate of conducted impulses is rather lowered than otherwise, or at any rate not increased. Quite in opposition to this is the extraordinarily increased stimulus formation in a tertiary center.

The foregoing observation may, I hope, serve to inspire greater attention to the occurrence of extrasystoles during cerebral affections. We may probably assume that such heterotopies are more frequent than might at first be suspected. Besides the considerable theoretical interest which the "central extrasystole" may claim, there is its practical significance. It may well be that, as Lucke has indicated, centrally produced disturbances in cardiac rhythm sympathetically involve the performances of the heart and that an affection of the heart of central origin is of essential prognostic significance in a primary cerebral disease.

SUMMARY

A brief review is given of our present knowledge of the possibility and the manner of origin of reflex and centrally originated extrasystoles. In this connection is presented the discussion of a clinical observation concerning the sudden occurrence of ventricular extrasystoles in a 58 year old man during an apoplectic insult with softening of the left half of the cerebellum. It is hypothesized that in this case the extrasystoles were originated centrally by means of a stimulatory effect on the medullary vagal nucleus. Finally attention is directed to the theoretical and practical significance of central extrasystoles.

THE IMPORTANCE OF EMBOLISM AS A COMPLICATION OF CARDIAC INFARCTION *

By GEORGE BLUMER, F A C P , *New Haven, Connecticut*

THE effect of sudden, non-fatal occlusion of one of the larger branches of a coronary artery is well known. The result, in brief, is the formation of an ischemic infarct involving that portion of the heart muscle supplied by the obstructed vessel, the so-called *myomalacia cordis*. The extent of this process depends on various factors, the more important being the size of the occluded vessel and the extent of development of vascular channels capable of taking part in the formation of a collateral circulation. The variability of the process is of practical importance at the bedside because certain clinical features are directly dependent on the presence of certain pathological changes. If the necrosis of the affected area of heart muscle does not involve the pericardium, localized pericarditis, a valuable clinical sign, does not develop. If the necrosis does not involve the endocardium lining the infarcted area, mural thrombi do not develop and secondary embolism, at least from this source, does not occur. It is well known that the necrotic process much more frequently involves the endocardial than the pericardial surface of the infarcted area. Wolff and White¹ state that mural thrombi almost always develop over the infarct. The valuable study of Meakins and Eakin² shows, however, that this statement is probably too sweeping, as mural thrombi occurred in only 46.7 per cent of their 62 autopsies. It is important to realize that, on account of the frequency with which the left descending branch is involved, both ventricles are frequently the site of mural thrombi, although Meakins and Eakin's figures indicate that they are about twice as common on the left as on the right side. It is clear, however, that in many patients who have suffered an occlusion there is an opportunity for the detachment of emboli from both ventricles and for their lodgment both in the pulmonary and the systemic circulations.

There is no doubt that some of the earlier writers on coronary occlusion failed to realize the importance of embolism as a complication of the resulting infarction. Other observers noted its occurrence and commented on it. Thayer³ in his article of 1923 clearly recognized the importance of the condition and diagnosed it during life. Gordiner,⁴ in his report on a series of 13 cases published in 1924, suggests that the sudden arterial plugging of the vessels of the brain, viscera or extremities indicates involvement of a branch of the left coronary, while signs of pulmonary infarct suggest involvement of the right coronary or its branches. Hamman⁵ in 1927, ap-

* Received for publication June 16, 1937

pears to have been the first to specially emphasize the significance of embolic phenomena, particularly in diagnosis, and since his article numerous authors, including Allan,⁶ Harrington and Wright⁷ and Parkinson and Bedford⁸ have stressed their importance

As might be expected, there is a decided difference between the figures covering the frequency of embolism based on postmortem examinations and those covering emboli diagnosed by clinical observation

TABLE I
Site of Emboli as Shown by Autopsy

| Author | No of Autopsies | Lung | Brain | Kidney | Spleen | Limb Vessels | Aorta | Mesenteric Artery |
|-----------------------|-----------------|------|-------|--------|--------|--------------|-------|-------------------|
| Meakins and Eakin | 62 | 47 | 4 | 14 | 9 | 11 | 2 | |
| Parkinson and Bedford | 83 | 7 | 1 | 9 | 8 | 2 | 1 | 3 |
| Wolff and White | 19 | | 2 | 6 | 2 | | | 1 |
| Total | 164 | 54 | 7 | 29 | 19 | 13 | 3 | 4 |

Table 1, covering 164 autopsies, shows that 130 emboli were discovered in the organs of the 164 subjects. This does not mean, however, that 130 out of 164 *patients* had emboli, because multiple emboli in the same patient are by no means rare. Table 2, covering 945 patients observed clinically,

TABLE II
Number of Patients with Clinically Detectable Emboli

| Author | No of Patients | No of Patients Showing Emboli |
|-------------------------------|----------------|-------------------------------|
| Anderson ⁹ | 9 | 1 |
| Blumer | 175 | 27 |
| Conner and Holt ¹⁰ | 287 | 42 |
| Gordinier | 13 | 3 |
| Howard ¹¹ | 165 | 17 |
| Hyman and Parsonnet | 51 | 17 |
| Levine | 145 | 17 |
| Parkinson and Bedford | 100 | 8 |
| Total | 945 | 132 = 13.9% |

shows that 132 or 13.9 per cent had embolic manifestations recognizable during life. Inasmuch as many small emboli fail to give rise to recognizable clinical phenomena and even fairly large emboli may be clinically latent, it seems certain that many more than 13.9 per cent of patients with coronary occlusion have embolism. However, it cannot be assumed that the clinical phenomena resulting from arterial occlusion in the brain, viscera or extremities are all of embolic origin. Some of them are doubtless due, as Meakins and Eakin point out, to thrombosis occurring coincident with or

subsequent to the coronary thrombosis. Owing to the difficulty of deciding, even on the autopsy table, whether a given lesion is thrombotic or embolic, exact figures as to the relative frequency of the two lesions are impossible to obtain, and, as a matter of fact, the decision is of academic rather than clinical interest.

A knowledge of the organs most frequently the *site* of embolism is of practical importance. Table 1, based on autopsy material, shows that the lungs are most frequently involved, followed by the kidneys, the spleen, the peripheral vessels, the brain, the mesenteric vessels and the aorta. Table 3,

TABLE III
Site of Emboli as Observed Clinically

| Author | No of Emboli | Lung | Brain | Kidney | Spleen | Ex- tremity | Periph- ery | Aorta |
|-----------------------|--------------|------|-------|--------|--------|----------------|----------------|-------|
| Blumer | 35 | 16 | 9 | 1 | | 6 | 3 | |
| Gordinier | 4 | 2 | 1 | 1 | | | | |
| Howard | 17 | 9 | 3 | 2 | | 2 | 1 | |
| Levine | 17 | 5 | 7 | 1 | 1 | | 2 | 1 |
| Parkinson and Bedford | 8 | 3 | 3 | 1 | 1 | | | |
| Total | 81 | 35 | 23 | 6 | 2 | 8 | 6 | 1 |

based on 81 collected clinical cases, shows that clinically also the lungs are most frequently involved, followed by the central nervous system, the vessels of the extremities, the kidney and surface vessels, the spleen and the aorta. It is obvious that pulmonary and cerebral emboli would be those most likely to be clinically recognized because they so frequently lead to obvious symptoms and detectable clinical signs. The same is true of occlusion of the arteries of the extremities, which usually causes readily recognizable and characteristic changes. Small emboli in the spleen and kidney could be much more readily overlooked, especially in patients so seriously ill as many of these patients are.

The *period* in the disease at which emboli are likely to occur varies within wide limits. In a collection of 40 patients with emboli observed by the author or taken from Levine's series¹² just 60 per cent showed evidences of embolism within 10 days of the occlusion. The remaining 40 per cent showed embolic phenomena between the eleventh and the thirty-eighth day. In some instances embolism occurred almost simultaneously with the coronary lesion, but this took place in only two out of 40 patients and it is possible that the lesions were thrombotic rather than embolic. Embolism on the second day is not uncommon, one such case seen by the writer occurred when the patient was unfortunately upset while being carried upstairs in a chair. The largest number of embolic phenomena occurred from the seventh to the tenth day. The number of cases with definite information as to the time of embolism is, obviously, much too small for accurate statistical purposes and these figures must be regarded as merely suggestive.

The *clinical manifestations* of embolism in these patients were the usual ones. In the pulmonary cases sudden pain in the chest, hemoptysis, cyanosis, shock and physical signs of local pulmonary change were usually present. In the cerebral cases the picture varied with the localization of the lesion, partial or complete hemiplegia, with or without aphasia, being the most common lesion in the severer cases. In some patients minor effects such as ptosis of one eyelid, visual hallucinations, strabismus or temporary amblyopia were observed. The involvement of peripheral vessels, almost always in the lower extremities constituted a serious problem when it occurred. Gangrene commonly resulted and frequently the condition of the patient was so poor that active surgical intervention could not be seriously considered and, on account of very low blood pressure, the use of vasodilators was hazardous. Involvement of the skin vessels was seen occasionally, resulting in superficial areas of gangrene. Sudden attacks of local peripheral pain without obvious signs, were present in one of my patients.

There is a small group of cases which require special consideration, i.e. those in whom embolic phenomena occurred months or even years after the coronary occlusion.* One patient, personally observed, had a cerebral accident, presumably an embolism a year after the occlusion. In one of Levine's patients a left hemiplegia developed eight months after the occlusion. Hyman and Paisonnet¹³ cite two patients who died of cerebral embolism one three years and one five years after a coronary occlusion. One can hardly assume, I think, that the emboli in these patients originated in a mural thrombus which developed over the infarcted area at the time of the attack, for the fact that these patients recovered from the attack made it probable that these thrombi became organized and harmless as a source of emboli. It is possible but not probable in view of the usual postmortem findings in healed infarction, that thrombosis is more likely to develop at the site of a former infarction than elsewhere, even years after the original lesion. It is more likely perhaps, that the emboli in these patients had their origin in intracardiac thrombi developing elsewhere in the heart as a result of poor circulation, just as they not infrequently develop in apparently well compensated cases of mitral stenosis. The question cannot be conclusively decided without more postmortem evidence.

The most important bearing which the question of embolism following cardiac infarction has is its influence on *prognosis*. It is certainly true that many of these patients recover from pulmonary infarcts but, as McNee¹⁴ has shown, the detachment of pulmonary emboli large enough to cause death may occur. Furthermore, there can be little question that the added strain associated with the development of one or more pulmonary infarcts may prove too severe a burden on the damaged heart. In my limited experience the development of cerebral embolism during the acute phase of cardiac

* These cases are not included in table 3

infarction has usually resulted disastrously. Recovery after late cerebral emboli may undoubtedly occur. Embolism of the larger vessels of the limbs has a most serious effect on the prognosis, for the impaired circulation and the low blood pressure encourage the development of gangrene and the outcome is commonly a fatal one.

So far as *treatment* is concerned, it would seem that the frequency with which mural thrombi are present in coronary occlusion serves to emphasize the necessity for prolonged and absolute rest during the acute phases of the process. It also justifies the attitude of many clinicians regarding the avoidance of medication with digitalis, unless there is some very definite indication for its use, such as auricular fibrillation.

The following conclusions seem justifiable.

1 In patients with cardiac infarction due to coronary occlusion mural thrombi are present over the endocardial surface of the infarcted area in about 50 per cent.

2 These mural thrombi may be limited to one cavity, but are frequently present in both the right and the left side of the heart.

3 Fragments of such thrombi are detached and produce clinically recognizable embolic phenomena in about 14 per cent of patients with cardiac infarction.

4 Embolism is most likely to occur during the first 10 days following a coronary occlusion.

5 Embolism of branches of the pulmonary artery is the most frequent type, but is less serious prognostically than cerebral embolism and embolism of the larger vessels of the extremities.

6 The frequency of such emboli emphasizes the importance of absolute and protracted rest and the avoidance of medication by digitalis, unless especially indicated, in the treatment of cardiac infarction.

KAPOK AND MOLDS AN IMPORTANT COMBINATION

By HAROLD C WAGNER, M D , and FRANCIS M RACKEMANN, M D ,
Boston, Massachusetts

IN a former study of kapok (" silk floss ") we¹ showed that a considerable number of patients with asthma have been relieved of their symptoms simply by eliminating kapok from the environment. We pointed out that the fibers of new kapok, freshly removed from the pod, have a high luster and resiliency, that extracts of them rarely give skin tests, that this kapok fresh and new, does little harm. Old kapok, however, which has been used as the stuffing of pillows, mattresses, and furniture, for some time, has a dull appearance. The fibers are dry and brittle, and readily break down into a fine dust. Extracts of old kapok give positive skin tests in many patients and the dust of old kapok is a frequent cause of asthma and other allergic disorders. The new and the old material have physical and chemical properties which are quite different and the content of the skin active principle appears to run parallel with the other properties.

What causes these changes due apparently to " age " in kapok? Van Leeuwen² believed that fungi were the causative agents. He observed that *Aspergillus fumigatus* which had been isolated from old kapok and which in itself gave negative reacting extracts, was able to convert non-reactive kapok into reactive kapok if it was allowed to grow on the non-active material. On the other hand, G. T. Brown³ in his recent studies on the importance of molds to allergy was unable to demonstrate any changes occurring in sterilized kapok after its inoculation with cultures of molds and other microorganisms including various species of *alternaria*, *aspergilli*, and *mucor*.

The observations of Cohen⁴ and his fellow workers with raw cotton suggest that other factors can be responsible. They found that non-reactive cotton which had been sterilized and kept sealed for several months became reactive. The changes had taken place in the absence of viable microorganisms, and moreover, as the materials were in sealed containers, it is doubtful whether other external factors such as oxygen or carbon dioxide could have been important in bringing about the changes observed. The evidence presented was more in favor of internal factors that were thermostable and which perhaps possessed properties similar to those found in enzymes.

These previous observations have not explained the clinical findings.

* Received for publication May 14, 1937.

From the Allergy Clinic and Laboratory, Massachusetts General Hospital, Boston, Mass.
Aided by the Eleanor Husted Leal Fund, Harvard Medical School, Boston, Mass.

There is need for additional studies, and in this present work, we have endeavored to investigate a few of the factors which we believed were important in the case of kapok.

EXPERIMENTAL

At the outset it was necessary to ascertain what effect sterilization by heat might have on the skin active principles of the various materials that would be used in the work. Suitable quantities of old kapok, old cotton linters, and of house dust, were sterilized for three hours at a pressure of 15 pounds per square inch. After cooling, each substance was extracted with Coca's solution and each extract was tested in the skin of seven patients. The skin tests with the extracts of the sterilized materials gave results which were in every case identical with the results of skin tests with extracts of the original unsterilized materials. Thus, whatever the skin active principle in old kapok, in old cotton linters, and in house dust may be, it is not affected by ordinary sterilization.

A second experiment was designed to study the effect of time alone on sterilized material. Cohen's experiment was repeated. Samples of kapok fiber obtained from the fresh opened pod were placed in large vials which were then sealed with rubber caps and sterilized for three hours in the autoclave. To equalize the inside and outside pressure of the vial during sterilization, a hypodermic needle plunged through the cap was used as a vent. At the end of sterilization, the needle was removed and the vials further sealed with melted paraffin. At this stage, the fibers as seen through the glass of the vial appeared to have lost some of their luster and to have darkened in color. The vials of sterilized new kapok were then placed as follows. One was set upon the window ledge so as to be exposed to the sunlight. Another was placed in a covered box that was put in a laboratory drawer. As a control for any possible changes occurring due to temperature, a third vial was placed in the rear of the laboratory ice box. All vials were left undisturbed for a period of six months. At the end of this time, the materials within the vials were removed, weighed, and extracted with Coca's solution on an equal weight volume basis. They were sterilized by Seitz filtration. All the extracts appeared alike and no visible difference could be noted between them and other extracts of freshly isolated pod kapok. Skin tests with the three extracts were made in 18 subjects who were known to give good skin reactions to old kapok but the results were entirely negative. Moreover, these same tests were repeated in 14 of the 18 subjects and again gave the same negative results. We thereby concluded that, at least within a period of six months, no significant changes had occurred in sterilized and sealed pod kapok whether it was exposed to sunlight, protected from light, or kept at temperatures of 8°, or at ordinary room temperature.

In a third experiment, the effect of dryness was investigated. A mode-

rate quantity of sterilized pod kapok was placed in desiccators over calcium chloride and over concentrated sulphuric acid. These likewise remained undisturbed for six months after which time the kapok was removed and extracted at once and taken to the clinic for testing purposes. In a series of 10 old kapok sensitive individuals, all extracts of the dried kapok gave negative results in all instances. Apparently prolonged exposure to a dry atmosphere does not cause any appreciable change in the skin reactivity of new kapok. If loss of moisture is the cause of breakdown in the kapok fiber, it alone is not the cause of the development of skin reacting factors.

At this point in the study, the supply of pod kapok gave out. (We were informed that the Dutch Government has prohibited the shipment of kapok pods and seeds from its colonial possessions.) We were forced to be content with the use of new kapok from a freshly opened bale*. This material, while not as inactive as the pod material so far as skin tests were concerned, was distinctly less reactive than old kapok.

In a fourth experiment, we sought to rule out the possible effect of oxygenation and carbon dioxide action. We reasoned that if either of these processes was important to the changes, an increased concentration might speed up the reactions so that their effects could be observed within a comparatively short time. To study this matter, three large Florence flasks were half filled with bale kapok and sterilized for three hours in the autoclave. After this treatment, we observed as before that gross changes similar to those mentioned in the case of pod kapok were present. The fibers had less luster and were of a darker shade of yellow. The flasks were allowed to cool over night and the next morning they were fitted with sterilized stoppers and tubing so that the atmosphere within the flasks could be easily changed. Into one of the flasks, cotton filtered oxygen was allowed to pass for a period of 15 minutes. The oxygen supply was then shut off and the feeding and exit tubes clamped tightly. In similar fashion, the atmosphere in the second flask was changed to carbon dioxide. The third flask was left sealed and served as a control. Thereafter, over a period of three months and at intervals of every three days, the oxygen and carbon dioxide in the first two flasks were renewed by the same technique. Meanwhile the flasks were kept at room temperature. At the end of three months, the material in each of the three flasks showed no changes in the gross appearances. It was removed and extracted. The three extracts were adjusted to an equal weight volume basis and were tested in 14 sensitive subjects. In all cases, it was impossible to distinguish any difference in the skin tests between the extracts of the material which had been exposed to either oxygen or carbon dioxide and that of the control. The evidence would indicate that the presence of concentrated oxygen or carbon dioxide alone over a prolonged period of time was not an important factor in activating relatively inert new kapok.

* The material was obtained through the courtesy of the Kapo Products Company.

In a supplementary experiment and with the purpose of additional control, oxygen and carbon dioxide respectively, were bubbled at rapid rates through extracts of old and new kapok for periods of two to eight hours. Skin tests with extracts treated in this manner gave results that were comparable in all respects with the untreated extracts. Apparently the skin active principle in kapok extracts is not easily, if at all, affected by continuous contact with pure oxygen or with pure carbon dioxide.

Meanwhile, other investigations of the possible effects of microorganisms were in progress. Extracts of the pure cultures of the common molds isolated from old kapok and described in a previous paper by Conant and the writers⁵ were tested on a group of 54 old-kapok-sensitive individuals. Ten patients gave moderately positive reactions with the extract of chaetomium species, nine with the extract of *Aspergillus niger*, nine with the extract of penicillium species, and seven with the extract of *Rhizopus nigricans*. These results are comparable to those of Brown³ and of Feinberg⁶ both of whom have tested large groups of allergic patients with extracts of the more common molds.

So far then, it has been demonstrated, first that extracts of new, unused, and freshly obtained kapok give negative skin tests, that this new material may be held in the laboratory under various conditions for considerable periods of time and still its extracts will give negative tests. Second, that extracts of the cultures of molds readily isolated from old used kapok gave positive skin tests in only a few of the old-kapok-sensitive patients.

Evidently, the many positive skin tests obtained with old kapok extracts depended neither upon the substance itself—the kapok fiber, nor upon the molds themselves that might grow in it. Perhaps, however, they depended upon the combination of molds plus kapok, that certain molds growing on this particular substrate would cause chemical changes which would result in the development of skin reactive principles.

To test this idea, the following series of experiments were carried out.

From Professor Weston we learned that certain molds have a predilection for certain substrates, that even in a single species, different individuals may have habits of growth which are quite different, one from another, and therefore, that it is important in any inoculation experiment, to use those strains which there is reason to think might grow well on the particular substrate. The idea of obtaining the inoculum by washing the old used material and using all the organisms obtained in the sediment was developed.

The procedure employed was as follows. Generous samples of the various old materials—old kapok, old cotton linters, and house dust—were wet down well with sterile salt solution (0.9 per cent) and the mixtures were allowed to stand and extract for approximately one hour. Then, the materials were stirred vigorously. The mass was squeezed in gauze and the dirty fluid was collected in a sterile container. The sediments were separated by centrifuging at high speed, adding increments of 40 c.c. of the fluid until a

sufficient amount of sediment had been secured. The supernatant fluids which contained extracts of old kapok, of old cotton linters, or of house dust, were discarded, but when later the sediments were washed in three changes of salt solution, the washings were saved and pooled for control purposes. The washed sediments were suspended in sterile distilled water and transferred to sterile atomizers from which they were sprayed in liberal quantities into flasks containing the substrate. These flasks were prepared in this way. Liberal quantities of kapok fiber from the bale, cotton fibers from new unopened bolls,* and finally, the fibers of commercial non-absorbent cotton, were finely cut with scissors, placed in florence flasks, sterilized in the autoclave, and finally spray inoculated. After inoculation with the spray, the mouths of the flasks were covered with inverted beakers and placed in large tin cans that were fitted with tight covers. To secure a high degree of humidity, the lower portions of each can were packed with moistened sphagnum moss. The relative humidity within the cans was checked at frequent intervals through two small holes in the covers and was always found to be above 80 per cent. In this experiment, all flasks were prepared in duplicate, and to eliminate the possibility of cross contamination, separate cans were used for each inoculum and its set of substrates. The cans were kept in the laboratory at ordinary room temperature. At the end of 60 days, one flask of each duplicate set was removed from the cans, the other flask being taken out after 120 days. Grossly, most of the flasks showed evidence of the growth of molds among the fibers—a few colonies black, yellow, green, or gray were seen here and there and more of them in the 120 day flasks, but the growth was not uniform or constant for any one sediment-inoculum or any one substrate. The heaviest growth seemed to be in the flask containing boll cotton which had been inoculated with old cotton-linter sediment, thus supporting the suggestion of Dr. Weston that certain molds have a predilection for certain substrates. Non-absorbent cotton seemed unable to support a growth of molds, for none of the flasks containing this material showed any gross change even after standing in the moist chamber for 120 days—and this was regardless of which particular inoculum was used. At the end of 60 days, the material in the first set of flasks was extracted by adding Coca's buffered phosphate solution to it and allowing the mixture to stand over night. The extracts were adjusted on a uniform weight-volume basis and were filtered first through paper and then through a Seitz wafer. At the end of 120 days, the second flask of each set was removed, examined, and extracted in the same manner.

Skin tests with the extracts were made as soon as they were prepared. Controls were provided as follows. Similar flasks of the vegetable fiber substrates were inoculated with mixtures of known mold cultures while others were inoculated with a bacterium—*B. subtilis* being chosen. Another set of flasks was placed in the moist chambers without any inoculation.

* The cotton bolls were obtained through the courtesy of The Murray Company, Dallas, Texas.

The sediment inocula were tested separately to see whether they alone might give skin tests. The washings of these sediments were pooled and saved as described, but skin tests with them were always negative. Each of the sediment suspensions was planted on duplicate dextrose agar slants, one set being incubated for 48 hours and the other for one week. At the end of these incubation periods, the whole cultures were extracted with Coca's buffered saline and the extracts passed through sterile Seitz filters. Skin tests with each extract gave negative reactions in a group of kapok-house dust-cotton linter-sensitive subjects.

TABLE I

Skin tests with extracts of bale kapok, boll cotton, and non absorbent cotton which had been sterilized first and then inoculated with dust sediments and microorganisms. Test subjects all skin sensitive to old kapok.

BK = Bale kapok BC = Boll cotton NC = Non absorbent cotton

The results of skin tests with the extracts of the inoculated flasks are shown in table 1

These results were not striking with any of the 60 day extracts and for the most part the reactions, where positive, were distinctly less than those given by the extracts of the corresponding old material. The greater frequency of positive reactions with the 120 day extracts is good evidence that the development of the active skin-test principle is associated with the amount of growth. The boll-cotton, cotton-linter sediment combination which showed the greatest amount of mold growth yielded extracts which gave the greatest number of positive reactions of any of the combinations. The negative reactions with the extracts of the controls indicate that the time element alone is not an important factor in the formation of the active principle.

The results do not show any relationship between the three inocula. Boll cotton inoculated with each of three sediments gives different results in each instance. This observation is interesting as the studies of Cohen et al. indicated that the active principles of house dust and old cotton linters had a common source. The negative skin tests with non-absorbent cotton however inoculated also indicates that the principle necessary for the growth of molds is similar to that necessary for the production of skin tests—the principle being removed in the manufacture of non-absorbent cotton.

Sterilized materials yielded only a meager growth after a period of 60 days. This raised the question whether sterilization in itself had affected the materials so that they became less suitable for the growth of molds. To investigate this possibility, the 60 day set of the previous experiment was repeated, using unsterilized materials. Inoculation with the common mold mixture and with the *B. subtilis* culture was omitted in this experiment, the controls being simply the unsterilized, uninoculated material which had been incubated in the same way. When this unsterilized material was inoculated with the mold containing sediments, a marked growth was obtained. Not only were there isolated colonies here and there between the fibers, but the contents of the flasks containing boll cotton and bale kapok all showed a dirty gray color with numerous black and yellow colonies. In contrast, the non-absorbent cotton flasks had no obvious growth and the uninoculated flasks showed no obvious growth.

The results of skin tests with extracts of the flask contents after incubation for 60 days in the moist chamber are shown in table 2. The results here are quite different from those obtained with the sterilized material. As the table shows, skin tests were not only positive but were often well marked. Bale kapok and boll cotton gave positive results in almost all instances and regardless of whether they were inoculated with the sediments obtained from old kapok, from old linters, or from house dust. If left uninoculated, however, the results were negative. This last is surprising because one would suppose that the crude material might contain in itself

molds of various sorts which would develop and produce changes similar to those in the inoculated material. Perhaps the time (60 days) was too short for full development or perhaps the samples obtained even though unsterilized were yet more or less free of the common molds. The former possibility is more likely. It is noted in this experiment also that non-absorbent cotton was not changed by mold growth sufficiently to produce a skin-test active extract.

TABLE II

Skin tests with extracts of bale kapok, boll cotton, and non-absorbent cotton not sterilized but inoculated with various materials. 60 day extracts. Test subjects all skin sensitive to old kapok.

B K = Bale kapok B C = Boll cotton N C = Non-absorbent cotton

These experiments demonstrate that the cause of the breakdown in the kapok fiber as well as the development of the skin test active principles in extracts of old kapok is the growth of molds upon the vegetable substrate. Skin tests with the molds alone are usually negative, skin tests with the kapok itself are negative, but when molds and kapok are combined, positive skin tests became easily demonstrable. The observations explain the clinical experiences previously described and point again to the great clinical importance, that is to say, the danger in the use of old kapok in the home. The same considerations apply to cotton linters. These vegetable fibers support the growth of molds and so develop skin test active principles. Non-absorbent cotton has, in the process of manufacture, lost something which is important for the support of mold growth as well as for the production of skin reactive extracts. Presumably, the same argument will

apply to all untreated fibers of vegetable origin in contrast to those of animal origin—like hair and feathers

SUMMARY

1 Steam sterilization of vegetable fibers (cotton and kapok) changes the material in some way so that molds will not grow well upon it

2 Time alone produces no change in kapok fiber which has been sterilized, regardless of whether this time be passed in the light, the dark, or the cold

3 Drying has no effect in producing the skin-test active principle

4 Oxygen and carbon dioxide have no effect even though the fibers are kept in the atmosphere of these gases for as long as three months

5 Molds, however, will cause changes in both boll cotton and bale kapok, especially if the molds are taken from samples of old kapok, old cotton linters and house dust. However, extracts of the inoculum itself give no skin tests

6 The skin-test active principle is directly proportional to mold growth so that

7 It is more marked in the 120 day cultures than in the 60 day cultures, and

8 It is much more marked when unsterilized material is inoculated

9 The experiments demonstrate that the active skin-test principle in commercial kapok depends upon the growth of molds in the kapok (vegetable) fibers

THE CLASS METHOD IN THE TREATMENT OF ESSENTIAL HYPERTENSION

By ROBERT W BUCK, M D , *Boston, Massachusetts*

WE are able to treat successfully such diseases as syphilis, allergic asthma or congestive heart failure because we have a good deal of accurate knowledge concerning their etiology and pathology, in the case of other conditions such as scurvy, malaria or pernicious anemia the lack of such knowledge did not prevent the discovery of a specific cure. Essential hypertension belongs to a third group of clinical entities, the etiology and pathology of which remain to a considerable extent obscure and for which there is no specific treatment. Fortunately perhaps, our profession has never permitted a deficiency in its knowledge of the exact nature of a disease to stand in the way of its therapeutics, so that there is no lack of suggestions for the care of the patient with hypertension. Ayman¹ collected within a decade over 200 accounts of procedures directed toward the relief of this condition. The remarkable fact is that they were all successful! He analyzed 35 of these articles in some detail, and found that practically every one reported complete or partial symptomatic relief, and in the majority a moderate to marked reduction in blood pressure was reported.

The "good results" obtained are not comparable to the cure of scurvy by the administration of orange juice or the relief of the symptoms of pernicious anemia by liver therapy. They consist in a subjective sense of improvement, the relief of a variety of symptoms, and a fall in the blood pressure level. All these results can be duplicated in patients treated only by suggestion, as Ayman has demonstrated. It does not follow that they are illusory. Such knowledge as we have of the etiology and pathology of hypertension is consistent with the clinically observed improvement which follows a variety of therapeutic measures if we consider that the two factors common to them all are sedation and the prevention or relief of vasoconstriction. Suggestion, by inspiring a sense of confidence as to the benefits of treatment, relieves worry, quiets the patient and permits him to relax. There is no good theoretical reason why suggestion should not thus accomplish sedation and vaso-relaxation as effectively (in kind and perhaps occasionally in degree as well) as luminal, alcohol, the nitrites, watermelon seed extract, mistletoe or surgery of the sympathetic nervous system.

I do not wish to seem to advocate suggestion as a method of stopping the pathological process which results in an arterio-capillary fibrosis or a

* Received for publication April 7, 1937

necrotizing arteriolar sclerosis, beyond the point suggested by many literal minded persons that "nervous tension" may possibly play some part in furthering the progress of such lesions. Confining ourselves to the consideration of the mere psychic benefit to the patient, it is pertinent to recall that the symptoms presented by patients with high blood pressure in its early stages are identically those complained of by psychoneurotic patients. Some observers have even concluded that "the early symptoms associated with essential hypertension are of psychic origin" ²

If we may conclude that sedation and relaxation are the two objectives to be sought in the treatment of our hypertensive patients, we are in a position to cease following the will o' the wisp of specific cure and to settle down to the development of a well planned therapeutic regime. Only thus can we rescue the hypertensive patient from the neglect that he now receives. Our interest in him must not be casual and intermittent, as it now is for the most part, but continuous and purposeful.

A method of demonstrated value in the treatment of the psychoneuroses might be expected to be helpful in relieving the symptoms of hypertension. The success of the "Thought Control" class established by Dr. Joseph H. Pratt ³ at the Boston Dispensary in redeeming a very considerable number of these patients suggested to us that a similar method applied to the treatment of patients with hypertension might be equally valuable.

Certainly the power of suggestion is "stepped up" when the suggestion is administered to a group. When a patient joins a group his individuality merges with it, and his individual resistance to suggestion is overcome by the contagion of the group response to its leader.

Again, the class method is helpful to the members of the group because of the morale which is developed in any association of persons working toward a common end. It is always difficult for the patient to carry out any regime of treatment "on his own." The difficulty is comparable to that of self-instruction in painting or drawing or gymnastics or Latin or mathematics. Class instruction encourages competitive striving for results, it causes the members to try to emulate those who are most successful, it develops a spirit of cooperation and enthusiasm which is possible only in a group with a common objective.

We have for several months conducted a "Hypertension Class" recruited from patients attending the medical clinic at the Boston Dispensary. The only requirement for membership is a high blood pressure. The attendance of patients with advanced renal failure is not encouraged, but neither is it denied them.

Our purpose is to present to these invalids a program of living which will enable them to consistently live at the optimum level of well being which is possible for them. This is in many or perhaps the majority of instances surprisingly high.

The program is built about a threefold approach which can be illustrated

graphically by a triangle each side of which represents one aspect of the treatment. This constitutes the Rule of the class (figure 1) and is demonstrated at each meeting.

By "Medical Care" we mean all treatment available in the clinic apart from participation in the class. This may be medical or surgical and in-

FIG 1 The Rule of the Class

cludes such matters as the treatment of varicose veins, or diabetes, sinusitis or congestive heart failure. We make no attempt to supervise or direct this adjuvant treatment, but prefer to permit the patient to attend to the care of his own needs as these are discovered by his regular medical attendant. We simply urge upon him the necessity for his giving ordinary sensible attention to his general health.

The second arm of the triangle, "Diet," is a rather arbitrary affair. To the average patient, a Diet is like Voltaire's God: if It did not exist, he should have to create It. I believe it is more desirable to build upon this hope than to antagonize our patients by denying the importance of a proper dietary. The diet chosen is advised first on the grounds that it may be essentially beneficial. It certainly is not harmful. People who by necessity followed this diet in the Scandinavian countries during the war years are reported to have shown a decreased mortality not only from hypertension but also from other diseases, especially those accompanied by degenerative processes in the cardiovascular system. This diet is that which Hindhede⁴ has promulgated for many years. It consists simply of potatoes, baked and eaten with the skins intact, dark bread and butter, milk, and apples or other fresh fruit. The members of the class are permitted to vary this rather Spartan, but on the whole well balanced and certainly economical fare by occasional mild lapses on holidays or when they go out to dinner and do not wish to be thought eccentric. If the diet is adhered to as well as most patients do adhere to it, we need not worry much about calories.

The base of the triangle is in fact the basis of our whole systematic method—the use of suggestion and psychotherapy. In the class this takes

the form first of education and explanation. The relatively benign course of essential hypertension is stressed, a plausible theory of its pathological physiology consistent with the knowledge we have is presented, and the importance of physical and nervous strain in the development of symptoms is emphasized. Abundant material is available here for many lectures, which are received with interest and appreciation, and more, with a feeling of reassurance and often the alleviation of fear.

Further, the psychic origin of the symptoms of early hypertension is explained. Without attempting any individual psychoanalysis, we simply point out over and over again the important rôle of the emotions, of apprehension and worry and unpleasant thoughts in the genesis of symptoms. The field here is too great to discuss within a paragraph. The fact is that all middle aged hypertensives (and many others) need a spiritual director, or call him a psychiatrist, or a personality worker if this seems preferable, and if as physicians we fail to utilize our opportunities in this direction we are not doing justice to our patients.

Finally, at each class meeting, the importance is stressed and the practice insisted upon, of regular and systematic relaxation. We should like to advocate that the "progressive relaxation" of Jacobson⁵ be developed and practiced by all of our patients, but the method is too time consuming and instruction in its use requires too much individual attention for it to be practicable. It is possible to obtain results with a less elaborate technic. We have a five minute relaxation period at each meeting during which all persons in the room are asked to individually follow the demonstration by the leader. Here again, it is difficult to convey briefly the really profound effect which can be attained by the proper conduct of this five minute period of complete silence and repose. The class members practice their "relaxation exercise" once, twice or three times daily, if they are able, during the week.

A feature which is important, and never omitted, is the giving of "testimony" by the older members. The success of those who have been practicing the tenets of the class is a powerful factor in starting the new members off in the proper spirit of optimism and earnest attention to the rules. Those who have benefited by their attendance are ever willing to stand up and say so to the other members of the group, and their testimony is more effective than any amount of lecturing or grave advice.

Our results over a period of several months have justified our expectations. Patients of course report the relief of such symptoms as dizziness, pain in the neck, hot burning sensations in the head, insomnia, and "shortness of breath." The uniformity with which they report that they "feel fine" (when formerly they presented a variety of symptoms) in itself testifies to a new mental attitude if not to any modification of the underlying pathological process. Some of our patients have shown no striking change in the level of their blood pressures, but in two-thirds of those who have

made three or more visits to the class a fall in pressure of from 18 to 46 millimeters of mercury has been observed

Our aim is not, however, primarily to reduce blood pressure, it is rather to aid these patients to attain an optimal level of well being. The approach is frankly largely psychologic. We feel that we have accomplished a worth while result if our patients lose their fears, adapt themselves to their condition and become optimists rather than pessimists, and we view our method as an application of well known and well tried principles rather than as a new form of treatment. In the clinic it enables us to utilize these principles far more effectively than they can be used in the individual interview.

PAROXYSMAL VENTRICULAR TACHYCARDIA REPORT OF THREE CASES, MECHOLYL USED AND INEFFECTIVE IN TWO

By NEUTON S. STERN, M.D., F.A.C.P., *Memphis, Tennessee*

THE comparative rarity of paroxysmal ventricular tachycardia, and the opportunity to report upon the ineffective use of mecholyl in proved cases suggested the presentation of these cases

CASE REPORTS

Case 1 S. B. C., female, single, aged 75, seen in consultation with Dr. Otis S. Warr. She was admitted to the Baptist Memorial Hospital December 25, 1936, for pain in her chest, cough and expectoration. Diagnosis was made of bronchopneumonia and hypertension, the blood pressure being 155 systolic and 110 diastolic on admission. Three days later she became semicomatose, cyanotic, with shallow breathing of the Cheyne-Stokes type. Blood pressure 135 systolic and 85 diastolic. An

FIG 1

oxygen tent was used with relief, and consciousness returned. On the following days the pressure varied from 104 systolic and 80 diastolic to 160 systolic and 108 diastolic, and once to 180 systolic and 90 diastolic. Breathing continued to be somewhat difficult. The findings by roentgen-ray suggested unresolved pneumonia with

* Received for publication June 18, 1937

clear areas possibly due to abscesses. The heart rate was rapid but regular, 100 to 120. Roentgen-ray therapy to the chest was tried January 5 and 8, 1937. On January 9, dyspnea increased, and the heart showed a gallop rhythm. The blood pressure tended to stay about 160 for the next few days. Dyspnea, tachypnea and râles in the chest indicated left ventricular failure, and the sudden attack of December 28 with drop of pressure suggested coronary occlusion.

On January 12, an electrocardiogram (figure 1) was made at the bedside. The ventricular rate was rapid, 167, the rhythm was regular, but the complexes showed slight variations in the length and shape of the principal deflections, and considerable

FIG 2

variations in the curve between these deflections. These variations were believed due to small P-waves superimposed on the ventricular complexes, falling at different times in the cycles, and were sometimes visible and sometimes buried. On this interpretation the auricular waves seemed to be regular and of a rate of 273. The interpretation of these electrocardiographic findings was Auricular flutter, complete A-V dissociation, ventricular tachycardia (probably nodal).

A similar curve was obtained on January 13

On January 14, the ventricular rate was very much slower (115) and the complexes had changed in shape (figure 2) The auricular rate was 286 The diagnosis was made of auricular flutter, with complete heart block In the light of this evidence it was believed that the rapid ventricular beat of the previous day had been due to paroxysmal ventricular tachycardia, the focus of origin being ectopic, below rather than in the node

FIG 3

On January 15, the electrocardiogram (figure 3) showed a ventricular rate of 105 Left axis deviation was present, T_1 was slightly upright, $T_{2,3,4}$ were not definitely discernible In Lead I, the P-wave was quite close (about 0.08-0.09 sec) to the ventricular complex, and the relationship was 1:1 This P was not retrograde In Leads II and III the P-R interval was markedly prolonged, being about 0.24 sec in Lead II, and about 0.26 sec in Lead III Possibly no block was present during the taking of Lead I, but more likely the conduction was so

delayed that each P induced not the ventricular beat immediately following but the next one. It was also possible that complete block still existed with auricular and ventricular rates very nearly the same, but the relationship altered between taking the leads as it might be made to by a ventricular premature beat.

FIG 4

On January 16 the electrocardiogram (figure 4) showed complete heart block. The ventricular and auricular rates were so nearly the same that it required many beats before the relative positions of P and QRS were definitely altered. This was probably the status on the fifteenth.

January 17 Heart rate 90

January 21 Died Autopsy not secured

Among the diagnoses were Paroxysmal ventricular tachycardia, paroxysmal auricular flutter, complete heart block, coronary sclerosis and occlusion.

Case 2 A P, male, aged 8, was seen in consultation with Dr W R Graves, December 19 1936. He had been seen on December 14 by Dr Graves. At that time he complained of abdominal pain and rapid heart beat. He was uncertain which came first. The pain disappeared in a few hours. His past history was negative except for scarlet fever one year ago.

Tachycardia was found, the heart rate varying in rate from 160 to 180 with slight irregularity present. An electrocardiogram taken at the Baptist Memorial Hospital revealed a tachycardia of ventricular origin. On December 19, the rate was still rapid, the apex beat was about 3 cm beyond the midclavicular line. A soft systolic murmur was present. The liver was slightly enlarged. No edema was present. After a test dose of quinidine sulphate of gr iii (0.2 gm) he was given four doses of 4 grains each at two hour intervals. The apex rate dropped to about 120. My electrocardiogram (figure 5) was taken at this point. Mecholyl (0.010 gm) subcutaneously caused vomiting, but was without result on the tachycardia. A few days later the paroxysm ceased spontaneously.

On January 15, 1937, the heart was only slightly rapid. There was a short squirty systolic murmur at the apex which was at the anterior axillary line. No râles were present, and no edema. Under the fluoroscope, the heart was seen to be

very large, with rounded borders, the left being close to the lateral border of the thorax. The electrocardiogram on this day showed left axis deviation.

About March 17, a paroxysm of tachycardia started accompanied by vomiting. Vomiting and the rapid pulse continued in spite of mechloryl, quinidine and glucose, and on March 19 he died. Autopsy was not secured.

FIG 5

Case 3 O. H., Jr., was first seen in 1932 at the age of seven. Two months before he had had influenza, followed by some exhaustion. Three weeks before he suffered an attack of tachycardia (rate over 200, rhythm regular) which lasted for two and a half days. He was given quinidine sulphate, and the attack stopped in a

few minutes (coincidence?) Two weeks later he had another attack which lasted 48 hours. It was not affected by quinidine. The rhythm was regular during the attack but irregular at the offset. The attacks seemed to be associated with mild digestive upsets, nausea and constipation. He had a skin eruption on the flexor surfaces of his forearms which came and went, and which the dermatologist, Dr E. R. Hall, thought to be allergic.

When seen by me there was no circulatory disturbance, and his physical examination was entirely normal. Fluoroscopy showed no abnormality. Electrocardiography (January 4, 1932) gave an entirely normal tracing except high T_1 (4.5 mm) and T_2 (5.0 mm).

He was seen again November 9, 1933. He had had three attacks of paroxysmal tachycardia in the previous three or four weeks, each lasting some length of time. Physical examination showed a heart rate of 112, a questionable systolic murmur at the apex which seemed to be just beyond the nipple.

On November 29, 1935, he was seen again. In the interval he had been examined by Dr. Hugh McCulloch in St. Louis, who it was reported thought the heart was slightly enlarged. On physical examination I found the apex to be 7 cm to the left of the midline in fifth intercostal space, palpable just beyond the nipple. The right border was 1.5 cm to the right. There was marked respiratory sinus arrhythmia. The sounds were normal. The rate was 72, the blood pressure 100 systolic and 60 diastolic.

The six-foot teleroentgenogram showed these measurements: RM 37 cm, LM 66 cm, T 103 cm, internal thoracic 19.5 cm, L 110 cm.

The electrocardiogram showed sinus arrhythmia, S_1 deeper (5 mm instead of 2.5 mm), and altered T-waves. T_1 was upright (5 mm), T_2 upright (5 mm) with slightly elevated RT_1 and 2 takeoff, T_3 inverted (1 mm), T_4 upright, and variable (from 2 to 4 mm). R_2 upstroke slightly slurred. Lead IV was taken from the left chest, fourth and fifth interspaces at left border of the sternum to the left leg.

During the following year, an attack was stopped in six minutes by meclocholyl 0.010 gm.

On November 18, 1936, he had an attack of tachycardia which lasted through the next day. Prior to this, he had had a cold with slight fever. During the year he had taken quinidine sulphate prophylactically, but recently had not taken any for several days. With the attack he had pain in the heart area like a hammer, "worse than an earache." He had had pain five times with attacks. The pain was not radiating. On November 21, another attack of tachycardia occurred, and pain began at once, subsiding later, leaving a bruised feeling.

On examination, the apex rate was counted as 176, and was sufficiently irregular to give the impression of auricular fibrillation. The blood pressure was 80 systolic and 60 diastolic. The first sound at the apex had a soft squirting quality.

An electrocardiogram was taken (figure 6) which showed a tachycardia of ventricular origin.

Meclocholyl 0.010 gm was given without result. The attack ceased the next morning.

On January 29, 1937, another attack appeared following a slight sore throat with fever (100° F) the previous day. Quinidine sulphate gr. i had been taken the previous evening and the morning of the attack. The attack ceased spontaneously just before he was seen, but an electrocardiogram was taken which showed a high T_1 (5.5 mm) with RT_1 takeoff about 1 mm high, a high T_2 (9 mm), cone shaped, with high RT_2 takeoff (1.5 mm), a high T_3 (3 mm) with RT_3 takeoff slightly high (0.5 mm), a diphasic T_4 (plus 4.5 mm, minus 1.5 mm).

On June 9, 1937, he was in good health. Pulse 76 and blood pressure 105 systolic and 60 diastolic. The pulse showed slight sinus arrhythmia. The sounds were nor-

mal The heart shadow on fluoroscopy suggested slightly the sabot shape The teleroentgenogram measured RM 3.5 cm, LM 6.7 cm, T 10.2 cm, L 13.3 cm, internal thoracic 23.4 The electrocardiogram showed T_1 upright (5 mm) with RT_1

FIG 6

takeoff only slightly elevated, a high T_2 (3.5-4 mm) with high RT. takeoff (1 mm), T_3 was inverted (0.5 mm) with RT. takeoff practically isoelectric, T_4 variable and diphasic (plus 1-2 mm, minus 1 mm)

The changes in this electrocardiogram, the abnormal T-waves and RT takeoffs, suggest that there is definite myocardial disease present in this boy

SUMMARY

1 Three cases are presented each showing a paroxysm of ventricular tachycardia. Each heart yielded evidence of organic heart disease, though such evidence is electrocardiographic only in Case 3.

2 Mecholyl was used in Cases 2 and 3, but was unsuccessful in terminating attacks that were proved to be of ventricular origin.

3 One case presented the paroxysm of ventricular tachycardia during an attack of paroxysmal auricular flutter, and later showed a complete heart block during the flutter, and with normal auricular rhythm.

AN ARTICLE CONTRIBUTED TO AN ANNIVERSARY VOLUME IN HONOR
OF DOCTOR JOSEPH HERSEY PRATT

OTTMAR ROSENBACH, PIONEER IN THE DEVELOPMENT OF THE CONCEPT OF FUNCTIONAL DISEASE AND FUNCTIONAL DIAGNOSIS IN INTERNAL MEDICINE¹

By HYMAN MORRISON, M D , *Boston, Massachusetts*

OTTMAR ROSENBACH holds a place among the notables in medicine by virtue of the part he played in the development of the concept of functional disease and functional diagnosis. This idea of recognizing and treating disease before structural pathology had actually taken place marks an epoch-making advance in internal medicine, historically in line with its several evolutionary stages.

First, there was the descriptive period dominated by Sydenham (1624-1689). A keen, painstaking observer, Sydenham re-introduced the old Hippocratic method of studying disease at the bedside and during epidemics, and grouped symptoms into clear-cut disease pictures previously undifferentiated or unrecognized.

The next stage began with Morgagni (1682-1771), founder of pathology, and reached its height during the first half of the 19th century in the clinico-pathological schools in France and England with the towering figure of Laennec. New methods of physical examination were invented, notably percussion and auscultation, many diseases were newly described, but more important was the correlation of clinical observation with pathological lesions demonstrated post-mortem.

In the middle of the same century a third step forward was made when physiological and chemical methods became an integral part of clinical investigation. Magendie in France defined medicine as "nothing but the physiology of the sick man" and similarly Virchow in Germany taught that "disease is nothing but life under altered conditions." It became insufficient to men like Traube merely to describe disease, nor would the lesions found in organs after death explain all the symptoms before death. Only by combining experimentation with observation and pathology could internal medicine attain the status of an exact science.

Then came the bacteriological era with Pasteur and Roux and Koch and Ehrlich and Behring. A new technic was developed, and stress was laid on etiology and specific therapy.

All along many new clinical entities were studied and classified. As they became more familiar, they came to be recognized not only in their typical or classical form, but also in their atypical guise, the *formes frustes*. Furthermore this trend led medical thought to concern itself with disease

¹ Received for publication March 17, 1937.

in its incipency, when alterations were only functional and not yet structural. In 1867 Kussmaul began to employ the stomach pump in gastric dilatation with stasis. In 1871 Leube studied gastric function with a test meal and demonstrated occasional deficiency of acid in the stomach. Others described gastric hypersecretion—permanent and transitory, and absence of hydrochloric acid in cases of gastric cancer. In the field of heart disease the term “cardiac insufficiency” was introduced about the same time by Von Dusch. These initial investigations were continued by Rosenbach, a

O. Rosenbach.

disciple of Leube, and it was he who first elaborated the concept of functional disease.

THE MAN—BIOGRAPHICAL DATA

Ottmar Rosenbach (b 1851, d 1907) was a native of Silesia, of Jewish parentage, the son of a physician, the nephew of Ludwig Traube and also related to Weigert, Ehrlich and Albert Fraenkel. After completing his medical studies at Breslau and Berlin (interrupted for a time by service in the Franco-Prussian War) he became assistant in the medical clinic at Jena in 1873 under Leube and Nothnagel where he remained for four years.

Among other studies, his experimental and clinical researches on the motor function of the digestive and circulatory apparatus, already initiated by his chief, were instrumental in inaugurating a new movement in internal medicine. He continued and elaborated this work in Breslau where he went in 1877, there he came under the influence of Julius Cohnheim. In 1887 he became medical director in the Allerheiligen Hospital, and in the following year extraordinary professor in the University. By this time he had attained eminence both as investigator and clinician, but in 1893 he resigned from the hospital and in 1896 from the University because of differences of opinion. He then moved to Berlin, where he remained to the end of his life, in 1907, devoting himself entirely, except for some consultation practice, to the writing up of previously completed scientific problems—"like an explorer, reaching home, putting in order, and classifying leisurely, the rich treasures he had collected during his travels."

HIS WORK AND MOTIF

In 1909, two years after his death, a selected collection of his writings, in two volumes, was published by Walter Guttman, friend and former pupil, including a biographical essay and a list of all his works. Even a brief perusal of this list will readily disclose that Rosenbach was a man of unusual energy and versatility, a fearless thinker whose interest reached out over the entire realm of medicine and beyond into the sciences, natural history, and philosophy. In all, 258 publications are enumerated, 14 in book form and the rest monographs and contributions to various periodicals and encyclopedias. Besides, there are mentioned many unpublished manuscripts on various topics—physics, chemistry, psychology, languages, and social medicine. This is the more impressive, when we are told that writing was a great task for him, that he would rewrite each work a number of times before it was published, that many manuscripts remained unpublished because they did not satisfy him, that he would even recall a work already in print for the same reason, that he kept on working to the very end in spite of several years of silent suffering from a malignant abdominal tumor and heart disease, and that all this was done in a relatively short span of life (1851–1907) aside from research, teaching, and hospital and consultation practice. But to work as long as one's strength would allow was the plan of his life, and even on his death bed it was his greatest concern that just those works which he considered most important—one on illusions and the other on certain physical and cosmic problems—were not completed.

I don't write merely for the sake of writing, or to create sensation, or out of desire to fight. I write for the love of science the tools of which are careful observation, extensive experience, logic and sober critique, and the object of which is the recognition and emancipation of the spirit from the yoke of tradition, and not the subjugation of mankind under the shackles of infallible authority. I write for love of the medical profession, whose true representative in my opinion is not the laboratory man, the theoretician or the specialist, but the physician in the fullest

sense of the word, who standing in the midst of life shows fullest sympathy for the patient (armed with the weapons of science but not tied slavishly to authority) I write from the point of view of the physician who recognizes that the suffering of man is an expression of unfavorable energy relationship or psychic influences which can be prevented or cured through no one point of view or method and only seldom through specific curative measures

I write, finally, out of the deeply rooted conviction that the laity also must not follow authority slavishly, but must be drawn only through study and example to better insight into all health problems. Insight will only then be complete when modern men will have learned again to sympathize with the patient to the highest degree instead of looking upon him as a source of contagion, shut out of human society in blind fear

This quotation is from the introduction to his book "The Problem of Syphilis", hence the last allusion. He detested the prevailing hysterical fear of contagion in syphilis, tuberculosis and other infectious diseases, leading to an almost total disregard of the importance of natural predisposition and resistance to infection

That he should speak in this manner was clearly justified by the wealth of his experience both in the laboratory and in the clinic and by the value of his concepts. Merely citing some representative topics from the list of his publications will give an estimate of the scope of his activity. By far the largest number of his contributions concern themselves with diagnosis, every phase of it to date was covered—physical, clinico-pathologic and pharmacologic, bacteriologic, neurologic and functional. He constantly emphasized, however, that "diagnosis must not be an end in itself or a means for systematic classification—it is the triumph of the art of medicine only when it furnishes a direct basis for prophylaxis and therapy"

In physical diagnosis there are papers on various aspects of auscultation and percussion and paracentesis, on the diagnosis of pleural exudate and on the effect of large pleural effusion on the circulation, on foreign bodies in the bronchi, on Cheyne-Stokes breathing, on cyanosis, on edema, on the diagnostic significance of reflexes, on pulsation of the liver and of the abdominal aorta, on carcinoma of the stomach, on Heberden's nodes, on intermittent hydrarthrosis of the knees, on the coincidence of tabes dorsalis and aortic insufficiency, on fever and antipyretics and thermometry, on chlorosis and other anemias, on diabetes and on the uric acid diathesis, on syphilis, on seasickness, and on epileptic and uremic convulsions. In 1893 there appeared his classic on "Diseases of the Heart and Their Treatment," and in 1903 a translation of his splendid monograph on "Diseases of the Pleura" in the American edition of Nothnagel's System of Medicine

Another group of papers is on clinico-pathologic and pharmacologic topics: studies on pigment formation in gastrointestinal and metabolic disturbances, on the significance of indicanuria, on tests for bile and glucose, on paroxysmal hemoglobinuria, and on albuminuria, on the antagonism between iodine and the salicylates, on sulphonal and amylhydrate, on the use and misuse of sodium bicarbonate, on chloral hydrate as a sedative in certain

types of dyspepsia, on the effect of digitalis on tissue and visceral tonus and on morphia

To neurology he contributed experimental studies in neuritis and on the physiology of the vagus, papers on hemiplegia, on paralysis of the recurrent laryngeal nerve, on the behavior of reflexes in sleep, on the mechanism of sleep, on cardiac neurosis, and on psychotherapy. Particularly noteworthy in this field was his work on the recurrent laryngeal nerves done in his earlier years at Breslau, when interestingly enough his first teaching experience was in the otolaryngological department because that happened at the time to be the only available position. It is noteworthy, also, because his intuitive power is here displayed to a high degree. On the basis of a single case carefully studied and on the critical analysis of similar cases reported in the literature he evolved in 1880 the now well known law "that in compression of the recurrent laryngeal nerve, first the dilators of the glottis suffer and only later are the constrictors involved sympathetically." With further clinical experience he amplified it to the effect that "frequently in affections of the nerve trunks or the central organs the flexors become paralyzed much later than the extensors." This work was recognized seriously only after Felix Semon confirmed it by independent investigation of a large number of cases.

HIS ATTITUDE TO BACTERIOLOGY AND TO EXPERIMENTATION IN MEDICINE

Although an aggressive opponent to the domination of medicine by the bacteriologic laboratory he recognized fully the biologic importance of bacteriology. "The value of bacteriology as a science cannot be over-emphasized," he said, "and it is capable of mestimable development." His very first publication in 1875 (after his inaugural dissertation in 1873 on a case of calculous pyelitis with perforation into the ascending colon) was on a new kind of grass green sputum, the color of which he demonstrated by cultural methods to be due to spores. Other papers were on malaria and cholera, and his controversy with Robert Koch on tuberculin involved a number of publications on tuberculosis and the tubercle bacillus. In a very stimulating book, "Aizt contra Bacteriologie," available in English translation, he sums up his attitude toward bacteriology and toward experimentation in medicine and also his general philosophy of medicine.

It took no small measure of courage to stand up practically single-handed against Koch, the latter then at the pinnacle of his career, to combat tuberculin as a therapeutic measure, or to disprove the statistics employed in claiming the efficacy of diphtheria antitoxin. But, though a most kind and generous man in personal relationship, he would never compromise in what he considered the truth. "No one will probably refuse to acknowledge that, uninfluenced by the fascinating opinion of the day, I have endeavored to discuss difficult problems from actual experience and in as many different lights as possible, with incisive criticism but objectively withal. The future will

decide whether I am right or wrong, and in what respect I have gone too far. Children who are now at play will in the end be our judges." Time did prove him correct in his controversy with Koch.

Just because he had experimented much, he warned against over-estimation of experimental conclusions, especially the drawing of conclusions concerning man from results on animals. "Injection diseases and infection diseases," he insisted "are two entirely different phenomena" and he early expressed his conviction that one must consider the clinic and observation at the bedside as predominant in the realm of human pathology. What reason can there be to assume identity of processes, when one taking place clinically shows in every case the effect of individuality and predisposition, whereas the case called forth by experiment does not at all manifest these factors? In disease caused by injection (experiment) there is scarcely any consideration of defensive and compensatory measures, whereas in human infection these factors appearing gradually produce a series of functional and structural changes. Only in a few infectious diseases, such as anthrax, acute military tuberculosis, and tetanus, is there an approach to identity between the disease process in man and in experimental animals. Even in these instances, in the case of the disease in man there are the phases of invasion, incubation, and gradual systemic involvement whereas in the experimental animal the organism is suddenly overwhelmed avoiding all defensive agencies, so that invasion and the height of the disease are almost synchronous. If it is considered, further, that comparatively enormous quantities of microbes are utilized for the injections, the differences between disease as observed clinically and disease called forth by experiment will be better appreciated.

I am fully aware that my criticism will be called a retrogression, but I am convinced that it is well-founded. I do not demand that exclusively one domain and one method of investigation should be cultivated, but I merely give it as my opinion that the clinic and the observation at the bedside should be considered the only scales by which results obtained through other methods of investigation must be measured. All laboratory methods, by whatever name they may be called, are only makeshifts, because they imitate disease artificially, they can touch only the extraneous aspect of matters. They may show some objects from a different view-point but they will never present the vital point, the origin and development of the functional disturbance, the ingenious compensation as manifested by the struggling organism under peculiar conditions. They can never be identical with the real mechanism and with the nature of regulative processes encountered as symptoms at the bedside. Experiment, correctly undertaken, enriches scientific knowledge, but it must not pretend to be the guide of practical action at the bedside, for it shows only the limits of compensatory capability, not the form of compensation. Much as I acknowledge the value of operative and exploratory proceedings in establishing correct views as to the functional capacity of various organs—I need only mention extirpation of the pancreas—it is well to keep in mind the limits of these methods of observation, and not to be persuaded that in the majority of these cases the test conditions in an experiment, ever so carefully conducted, may in any wise imitate or be a substitute for slowly progressive changes manifested by disturbances of function which are called disease.

FUNCTIONAL DISEASE AND FUNCTIONAL DIAGNOSIS

Rosenbach's work which particularly influenced medicine dates back to his early years. In 1878, when he was only 27, he contributed two papers which, as previously mentioned, inaugurated formally the new trend in internal medicine of thinking of disease in its earliest manifestations when there is still functional disturbance only and before there is structural or organic change. The first paper entitled "The Mechanism of Gastric Insufficiency" was the result of the work he had carried on at Jena under the influence of his former master Leube.

The crux in the diagnosis of gastric function, digestive as well as motor, is not in the determination of the size of the organ, for this furnishes only uncertain and late criteria. When a stomach is so dilated that its size is undoubtedly abnormal, and its digestive function, as indicated by undigested food content, is so definitely impaired as to make the diagnosis simple the best that can be hoped for is an arrest of the process, but not improvement. If we desire to cure we must set ourselves not to make a diagnosis of an irreparable pathologic condition, but rather to recognize early the origin of the affection, the beginning of the process, the *functio laesa* of the organ, and because of this we must lay the main emphasis on functional diagnosis. Medicine as far as possible must free itself from the dominance of the viewpoint of pathological anatomy.

Dilatation of the stomach is not a completed state in the anatomical sense, but rather a gradual process, and we can obtain information on the first stages or milder forms not through anatomical measurement of the size of the organ, but rather through testing physiologically its functions. Just as we cannot reach a conclusion on the strength of the heart from its size, but must consider the tension and quality of the pulse so it is impossible without careful investigation of the efficiency of the stomach to draw a conclusion as to its strength merely through measuring its dilatation.

There is no way of knowing exactly when a stomach is larger than normal. The size of this organ can only be of diagnostic value if it changes under observation. It must be clear then that the stomach will undergo dilatation only when there is a discrepancy between its expelling motor force and an undue resistance. Muscular hypertrophy will compensate for a while the entailed increased work. But as soon as the obstruction is too great or too prolonged, no longer controllable by increased work, there must occur a stretching of the stomach wall through ingested material and the stretched and overburdened muscle fibers get into a more or less parietic state. But this weakness occurs not alone through mechanical stretching but often through coincident nutritional disturbance of the muscles. Incidentally I want to note that such functional disturbance of the gastric musculature of even high degree will only seldom show microscopic changes—the same is true in the case of heart weakness.

Disproportion between expelling motor capacity of the stomach and increased effort-demands leading to its enlargement may be due either to obstruction or to catarrh, or to unusual amount or quality of food hurriedly ingested, in addition there may be the congenital weakness of the stomach wall or that acquired during acute infections and upon the degree of paresis of the stomach will depend the extent of the disability, also it is evident that the instances of stomach dilatation hitherto recognized represent but a late end-result of a series of transitory dilatations. A sharp distinction must be made between functional or relative and permanent or absolute dilatation. A large stomach may be normal while a much smaller one may already

clearly show functional disturbance under certain strain. In other words, dilatation of the stomach depends on the efficiency of the musculature and the extent of excessive resistance. With increase of one or diminution of the other there will intervene an insufficiency of the expelling motor forces, resulting in a relative insufficiency of the stomach. Overstepping the functional limits of the stomach, capable to cope with the ordinary tasks, will result in a relative insufficiency which sooner or later will invariably become absolute. So the center of gravity of diagnosis is not in the size of the stomach but in the functional test of its expelling motor force. It seems better thus to choose the name gastric insufficiency for disease phenomena and to reserve the term dilatation for irreparable, end-results of gastric insufficiency.

What are the methods of making a diagnosis of gastric insufficiency? First there is inquiry into the patient's symptoms due to food and eating habits, also the study of vomitus, if present. Then there is the study of gastric contents by means of the stomach tube according to Leube before and after test meals, or at times after indigestible food such as dried berries has been eaten. Sometimes succussion sounds two or three hours after a test meal may be studied, or the rise and fall of the level of the stomach contents is reflected through a speculum, or through sounds produced in the stomach, through compression with inflatable balloons introduced through the stomach tube, or the contractility of the stomach may be tested by filling and emptying the stomach with water. Through these investigations disturbances of the digestive and motor capacity of the stomach can be determined and measures instituted for their correction through appropriate diet in divided quantities.

So the therapy of gastric insufficiency will depend directly on an early exact diagnosis. And, furthermore, by developing this mode of investigation we may succeed in approximating the diagnosis of diseases of the stomach to that of the chest. To attain this objective we must not, however, shun new methods even though it may at first seem as unnecessary as did percussion and auscultation to our predecessors for we may hope for more happy therapeutic success in diseases of the abdomen because of easier accessibility than in the case of diseases of the chest.

The other paper which appeared in 1878 was entitled "On Experimental Cardiac Valvular Deformities." It was produced under the stimulus of Julius Cohnheim and read as his habilitation thesis when he became privatdozent at Breslau. Working with rabbits and dogs he produced artificially lesions of the heart valves, and found that severe insufficiency and stenosis of the valves could not change the arterial blood pressure, that compensation intervened at once. He attributed this capacity to "the latent reserve force of the heart muscle," a term original with him. "It is, therefore, experimentally established that there is a compensatory mechanism in the heart which can straighten out sudden disturbances in the balance of the circulation." In the same work he attempted also to show when and under what conditions endocarditis may be produced, and to answer what bearing these experiments had on questions of clinical interest.

This concept of insufficiency of organs and a compensatory mechanism through latent reserve force became the "leit-motif" throughout his unusually rich career, and in succeeding years he also described insufficiency of the intestinal tract, and applied this same concept to the kidneys, the nervous system and to disturbance of metabolism such as diabetes and obesity. The physician must not wait until permanent dilatation of the stomach or

heart has occurred or paralysis of the intestines. His aim must be to recognize insufficiency, or the state of disproportion between the demand on an organ and its ability to perform the work. Functional diagnosis must be developed as contrasted with the anatomical form, so that disease may be recognized in its incipency, in the transition from fatigue to actual change in the tissues and organs. A cure may be achieved then by lessening the load on the organ—impossible after permanent changes have set in.

Diagnosis should not be an end in itself nor a means of systematic classification but should at all times aim for a balance of energy, it is the triumph of medical art only when it furnishes a direct basis for prophylaxis and therapy. Medical efficiency is not based on the diagnosis of mitral insufficiency or fatty heart, but on the decision as to what is the cause of the disturbance, on the extent of functional disturbance of valve or muscle, on how strong the compensatory forces are, and under what conditions an early disturbance of balance can be restored.

Diagnosis, then, was to Rosenbach but an instrument for better understanding of life in general, so as to enable the physician to see the human individual as a harmoniously well balanced dynamic organism.

The physician of the future will be compelled to consider, above all, prophylaxis, the rational distribution of the products of internal and external activity—i.e., the correct alternation of rest and labor, the appropriate adaptation to changes of the external conditions of life, and the harmonious development of all physical and mental functions. He will not, in the frame of a formal diagnostic systematism, as a cellular pathologist grasp after symptoms pathognomonic of local changes of tissue, but he will endeavor, as a biologist, to obtain a broad view of the realm of energetics (the province of which is modern organic physiology) and of the total balance of phrenosomatic activity.

HIS PLACE IN THE HISTORY OF MEDICINE

Even the fragmentary bits of his life and work recorded here stamp Ottmar Rosenbach as an extraordinary figure in medicine. Yet how little was he appreciated in life, and how few know him now! Partly, this was due to his nonconformist personality. Celibate, retiring yet unusually generous and understanding and genial in a small circle of friends, finding solace with his heroes Heine, Schiller and Goethe, Schopenhauer, Kant and Spinoza, he was almost eccentric in his devotion to medicine. But he was a keen, prodigious investigator, a great clinician, and a fearless, original thinker. He was not always right, in his great zeal to prevent and cure disease by recognizing it in its incipient stages he often failed to recognize the importance of etiology in disease. Nevertheless his original concepts, worded originally, have become thoroughly integrated in our clinical thought and speech. Especially profound and stimulating in its influence on the development of internal medicine was his concept of functional disease and functional diagnosis. For this he holds a notable place in the history of medicine.

CASE REPORTS

GENERALIZED ACTINOMYCOSIS, REPORT OF A CASE *

By MORTON F MARK, M D , and OSCAR AUERBACH, M D ,
Staten Island, New York

SINCE Israel's ¹ original paper in 1878 on actinomycosis in man, the disease has been observed with increasing frequency so that it can no longer be considered the rarity it once was. Even as far back as 1899, Ruhrah ² collected 58 cases that were reported in America, and, reviewing the literature, he found a total of 1094 cases. Of these 56 per cent were of the cervico-facial type, 20 per cent gastrointestinal, 15 per cent pulmonary, 2 per cent skin, and 6 per cent were doubtful.

Numerous reports have followed these early contributions, but few indeed have been the cases of generalized actinomycosis. In 1925 Sanford and Voelker ³ reviewed 670 cases of actinomycosis that had been observed up to that time in the United States. Of these, in only 13 was there a generalized involvement. In 1925 Werthemann ⁴ collected four cases of actinomycosis with generalization and added two of his own. A number of other reports have appeared in the literature, notably those of Becker, ⁵ Schinz and Blangey, ⁶ Shapiro, ⁷ Kasper and Pinner, ⁸ Fried and Light, ⁹ Fellingner and Salzer, ¹⁰ and others.

Despite the fact that the generalized form has been reported in the literature in a number of instances, this type of actinomycosis is still rare enough and of sufficient interest to warrant the addition of another case, particularly so since the diagnosis was made ante-mortem.

CASE REPORT

Clinical History J C, a white male laborer, aged 47, was admitted to Sea View Hospital June 27, 1936. In February 1936, the patient had developed cough, expectoration, and fever. The cough, moderately severe in character, persisted for several weeks. It then abated somewhat, but a slight cough continued. In April a tender red swelling appeared on the lateral surface of the right lower leg. This was incised, but failed to heal, and continued to drain a thick greenish-yellow pus. In the latter part of April, the cough and expectoration became much worse and on one or two occasions he expectorated a little blood. In May an abscess appeared on the left arm and a week later another abscess developed over the right buttock. In the latter part of May 1936, the patient developed constant dull pain in the right lumbar region associated with chills, sweats, frequency, urgency, nocturia, burning on urination, and a temperature ranging between 102 and 104°. On June 16, 1936 he was admitted to a City General Hospital. There, the abscesses over the buttock and left arm were incised, but continued to drain. Because of the pulmonary symptoms, and because of a chest plate showing a density at the right apex, a diagnosis of pulmonary tuber-

* Received for publication February 26, 1937.

From the Departments of Medicine and Pathology, Sea View Hospital, Staten Island, N Y

culosis and possible right pyelonephritis was made and the patient was transferred to Sea View.

Physical Examination On admission to Sea View Hospital, physical examination revealed a poorly nourished adult male who appeared acutely ill. The teeth were carious. There were impaired resonance and diminished breath sounds at the apex of the right lung. The blood pressure was 114 systolic and 70 diastolic. The heart and abdomen were negative. There was an ulcer on the left arm about one inch in diameter from which a small amount of greenish-yellow pus exuded. The skin margins of the ulcer showed a reddish-purple discoloration, and the surrounding tissue was indurated. A similar ulcer, about two inches in diameter, was seen over the right buttock, and a third was noted on the right lower leg. There was an exquisitely tender swelling in the right lumbar region and the Murphy sign was positive.

Laboratory Findings The sputum was persistently negative for tubercle bacilli. The urine was clear, specific gravity 1.018, albumin one plus. It showed, microscopically, many clumps of white cells, a few red blood cells, and occasional granular casts. The blood hemoglobin was 51 per cent. There were 2,820,000 red blood cells and 16,800 white blood cells. The differential smear showed 88 per cent polymorphonuclear leukocytes, 6 per cent lymphocytes, and 6 per cent monocytes. The blood chemistry was normal. Blood cultures were negative. The sedimentation rate was 115 mm in 45 minutes. The Wassermann test was negative.

Roentgen-Ray The posterior anterior view of the chest showed an opacity in the region of the right apex. This was interpreted as being due to a thickened pleura (Figure 1). Roentgenograms of the bones underlying the cutaneous ulcers showed no evidence of bone involvement. The spine was negative.

Course The temperature was hectic in character, and ranged between 98 and 102°. The pulse rate was 80 to 100. Frequency, urgency, and right lumbar pain were prominent symptoms. On June 30, he developed severe persistent frontal headache. The next day the patient vomited twice. Neurological examination on July 2, 1936 revealed nuchal rigidity and positive Kernig and Brudzinski signs. The cranial nerves were not involved. The deep reflexes were bilaterally markedly exaggerated, and ankle clonus was present. There was a suggestive Hoffman sign on the left, but the other pathologic reflexes were negative. Bilateral choked discs were seen. The spinal fluid was clear and the pressure was 10 millimeters of mercury. The Pandy was positive. There were 320 cells predominantly lymphocytes. The spinal fluid sugar was 37 mg and the chlorides were 610 mg. On July 3, the patient was comatose. Neurological examination at this time showed in addition to the previous findings, bilateral positive Babinski signs. A spinal puncture was again done. The fluid was under increased pressure, cloudy, and contained 1900 cells per cubic millimeter of which 95 per cent were polymorphonuclear leukocytes. On the same morning an aspirating needle was inserted into the swelling in the right lumbar region and 20 c.c. of thick greenish-yellow, very foul smelling pus were removed. On more careful examination of the pus numerous small yellow granules were observed. These granules, when crushed under a cover slip and examined microscopically, were found to consist of mycelial threads with clubbed ends. The patient died at 5 p.m. on July 3, 1936.

The clinical diagnosis was Pyemic form of actinomycosis, multiple actinomycotic brain abscesses and meningitis, actinomycotic perinephritic abscess, multiple actinomycotic abscesses of the skin.

Necropsy The necropsy was performed 16 hours after death. The body was that of an emaciated adult white male. The subcutaneous ulcers previously described were observed on the upper portion of the left arm on its lateral surface, over the right buttock, and over the external malleolus of the right leg. The underlying bones were not involved.

The right lung was firmly adherent at the apex to the chest wall. The left lung was free. The pleurae over the apex of the right lung were adherent and thickened, measuring 2 cm in thickness. In the apex of the right upper lobe, the lung tissue for a distance of 1.5 cm from the pleura was firm, flat, grayish-black in appearance, and non-resilient. Just beneath this area and under the lateral pleura there was an emphysematous bleb measuring 1 cm in diameter. The lung tissue of the right middle lobe was well aerated for the most part. Situated just above the interlobar fissure

FIG 1 Roentgenogram of chest showing an opacity at the right apex. At autopsy this opacity was found to be due to a non-specific fibrosis. The primary actinomycotic lesion found at autopsy in the right middle lobe is not visualized.

and 6 cm from the lateral pleura, there was a soft yellow mass 1 cm in diameter. This was well encapsulated (figure 2). There was no change in either of the lower lobes. An emphysematous bleb measuring 2 cm in diameter was seen just beneath the apex of the left upper lobe. The tracheobronchial nodes were enlarged.

Surrounding the right kidney there was a large abscess cavity measuring 10 cm in diameter. This was filled with thick putrid yellow-green pus. In the posterior portion of the kidney substance near its upper pole there was an irregular soft yellow mass measuring 6 cm in its longest diameter. This was composed of necrotic and

purulent material. It communicated with the previously described large abscess and also with the renal pelvis (figure 3). A small amount of pus was present in the right renal pelvis and ureter.

FIG. 2. Gross specimen of right lung showing small primary actinomycotic focus in middle lobe.

On opening the dura, a small amount of thick green pus was seen over the occipital and right frontal regions. The meninges were markedly congested. In the anterior portion of the right frontal lobe two abscess cavities filled with greenish-yellow pus were noted. The larger measured 2 cm and the smaller 1.5 cm in diameter. A similar abscess 1 cm in diameter was found in the right parietal lobe and another in the cortex of the left occipital lobe (figure 4).

FIG 4 Section of brain through occipital lobe showing actinomycotic abscess

Histopathology

Lung In the section of lung through the small yellow mass described grossly, there was an abscess composed of a dense accumulation of polymorphonuclear leukocytes with a few lymphocytes and large mononuclear cells. At the periphery of this abscess a ray fungus was seen. This consisted of a central granular mass with peripheral club formation. In the Gram stain, the central mass was seen to consist of branching mycelial threads. The abscess was surrounded by granulation tissue composed of epithelioid cells, fibroblasts, lymphocytes, and collagen fibers.

Kidney In the section of kidney there was an abscess composed of polymorphonuclear leukocytes, nuclear remnants, lymphocytes, and large mononuclear cells. Several ray fungi were seen (figure 5). These were similar in character to those described in the lung. The wall surrounding the abscess was larger in diameter than

FIG. 5. High power section through kidney abscess showing ray fungus.

that seen in the lung and was composed of lymphocytes, epithelioid cells, and polymorphonuclear leukocytes. Very little fibrous tissue was seen.

Brain Abscess In this section an abscess was seen which was composed chiefly of polymorphonuclear leukocytes, but also of lymphocytes, and nuclear remnants. Occasional ray fungi were present. The wall of the abscess contained epithelioid cells, lymphocytes, fibroblasts, large mononuclear cells, and a few polymorphonuclear leukocytes. Within the cytoplasm of the large mononuclear cells fat droplets and necrobiotic nuclei were observed. Collagen fibers were present in moderate amount at the periphery of the wall of the abscess. In the leptomeninges the blood vessels were engorged and there was a dense infiltration of lymphocytes, large mononuclear cells, and occasional polymorphonuclear leukocytes.

Skin Ulcer In the corium as well as in the subcutaneous tissue there was a collection of lymphocytes, mononuclear cells, epithelioid cells, fibroblasts, and a few polymorphonuclear leukocytes. The capillaries were engorged.

Anatomic Diagnosis Primary actinomycosis of the right middle lobe of the lung, generalized actinomycosis with actinomycotic abscesses in the brain, right kidney, and skin, actinomycotic meningitis, actinomycotic right perinephritic abscess, fibrosis of the apex of the right lung (non-specific), emphysematous blebs in both lungs, dilatation of the heart, diverticulum of the rectum

COMMENT

For many years the dispute over the etiology of actinomycosis revolved itself around the question as to whether the organism was the anaerobic one of Wolf-Israel¹¹ or the aerobic one of Bostroem¹². Bostroem's organism is exogenous and is found widely distributed on grain and plants. The Wolf-Israel type is anaerobic, grows at a temperature of 37 degrees and will not grow at room temperature. Wright¹³ obtained cultures of the anaerobic organism from clinical cases of actinomycosis and concurred with Wolf-Israel in their conclusion that the anaerobic organism was the etiologic agent. In 1910 Lord^{14, 15} found organisms with the morphological and staining reaction of actinomyces in carious teeth and in tonsillar crypts of normal individuals. When this material was injected intraperitoneally into guinea pigs, it gave rise to tumors which histologically were similar to actinomycotic tissue. He concluded that the buccal cavity was a normal habitat of actinomyces and was the source of infection. As a result of this work the previously widely accepted conception that chewing infected grain or straw led to actinomycosis was quite generally abandoned, and the aerobic organisms were considered entirely saprophytic.

Naeslund¹⁶ after extensive investigation with various strains of both aerobic and anaerobic organisms has found that there are pathogenic and non-pathogenic strains of each type. He thus divides the pathogenic actinomyces into two groups, actinomyces-alpha and actinomyces-beta and gives the following characteristics for each.

Actinomyces-alpha Found in the mouth and gastrointestinal tract of normal individuals and not found free in nature. It is chiefly anaerobic, grows best at body temperature, and little or not at all at room temperature. It is rarely acid fast, never forms spores, and shows little resistance to drying. It forms long threads and clubs in the body and usually shorter rods on artificial media. Growth on agar is very slight. It is quite pathogenic for cattle but only slightly so for guinea pigs and rabbits. Its portal of entry in the human body is the mucous membrane of the mouth and intestines, and less often the lungs. It usually produces actinomycosis of the cervico-facial type and of the gastrointestinal type and rarely of the lung. Spread of the disease occurs by direct extension. Generalization through the blood stream is rare. The clinical course is, as a rule, mild. There is little or no fever and the prognosis with treatment is good.

Actinomyces-beta Found free in nature, is aerobic, and grows well on agar at room temperature. Spore formation is common. It forms long threads in the body and on media, but club formation is not common. It strongly resists drying. It is quite pathogenic for guinea pigs and rabbits and less so for cattle. The portal of entry in the body is usually the lung and less often the skin. The fungus reaches the lung either by means of inhalation or by aspiration from the mouth. It, as a rule, produces actinomycosis of the lungs and

spreads by direct extension and by metastases through the blood stream. The course of the disease is relatively rapid and usually fatal.

The two types, however, can not be too sharply demarcated since cases have been reported in which the organism could be grown both aerobically and anaerobically (Naeslund,¹⁶ Fellingner and Salzer¹⁰).

In our case, we were unsuccessful in obtaining a pure culture although numerous attempts were made under both aerobic and anaerobic conditions and with several types of media.

The primary lesion in the generalized form of actinomycosis is, in the very large majority of instances, located in the lung. In a review of 20 cases described in the literature and including our own, the primary lesion was in the lung in 15, in the cervico-facial region in two, and in three it was doubtful. Although the lower lobe is usually the seat of the focus, it not uncommonly is seen in the upper lobe.

The size of the primary lesion as observed at autopsy varies greatly. It may be very small, in fact, so small that it can be missed entirely unless carefully searched for. In our case the small focus was not found at autopsy until the second examination of the lungs was made. Even the roentgen-ray plate of the chest, perhaps because of the anatomic location of the nodule, did not reveal evidence of its presence. It is extremely important to keep this fact in mind. Several cases of primary actinomycosis of the brain have been reported (Howard¹⁷) although it is most difficult to explain how this organ can be the primary seat of the disease. As Jacoby¹⁸ points out, it is quite possible that in these cases, either the true primary lesion was missed by the pathologist, or else the patient had a small primary lesion during life which was not observed by the physician and subsequently healed. The evidence for the conclusion that the pulmonary lesion was the primary one in our case is that, in the first place the pulmonary symptoms were the first to appear, and secondly, the anatomic character of the lesion observed at autopsy indicated that it was the oldest in the body.

The primary lesion can and very frequently does spread by direct extension to involve a large portion or the entire lung. It may extend by continuity to the pleura producing an empyema, into the chest wall with the formation of an abscess, and into the pericardium and myocardium. Progression by way of the lymphatics is denied by most authors. The lymph nodes are usually enlarged and edematous, but rarely show evidence of the actinomycotic process. In a case reported by Werthemann,⁴ however, the tracheo-bronchial glands were definitely involved. Generalization by way of the blood stream in instances of primary actinomycosis of the lung does not appear to be very uncommon. The organisms invade branches of the pulmonary veins and thus enter the general circulation. Kasper and Pinner⁸ and Fellingner and Salzer¹⁰ both demonstrate beautiful histological sections which show the ray fungi within the pulmonary veins.

Metastases may be wide spread, involving many organs, or they may be very few in number. The brain was the most common location for metastases in the cases reviewed, being affected in 15 of the 20 cases. In the order of decreasing frequency, metastases occurred in the kidneys, the skin and subcutaneous tissue, the spleen, the lungs, the heart, the liver, the bones, the thyroid,

the intestinal wall, the lymph nodes, and the testicle. There were three perinephritic abscesses in the 20 cases. It is interesting to note that metastatic involvement was greater in those instances in which there was involvement of the heart.

When the brain is affected metastatically in generalized actinomycosis, abscess formation is the most frequent type of lesion. There may be one or several abscesses, and there appears to be no predilection for a particular lobe. The meninges can be secondarily involved. Abscess formation was present in 13 of the cases reviewed. In one (Fellinger and Salzer¹⁰) a subarachnoid granuloma was seen, and in another (Snook¹⁹) the meninges alone were involved. This is contrary to the findings noted in actinomycosis of the central nervous system resulting from direct extension of an aural lesion. In these, meningitis is frequent and abscess formation less common (Moersch²⁰).

The heart and pericardium may be involved by direct extension or by the hematogenous route. When the blood stream is the avenue of approach, numerous small abscesses are found in the myocardium. One of these may break into a chamber of the heart and thus provide a second source of dissemination. When the spleen, liver, thyroid, intestine, and lungs are affected secondarily, many small abscesses are generally found. In the intestine they are seen within the wall. The kidneys may show multiple small abscesses or there may be a single large abscess in the cortex of one kidney which extends into the pelvis, or peripherally, giving rise to a perinephritic abscess. Bone can be invaded by direct extension from a neighboring organ, but in most instances actinomycosis of the skeletal system is the result of a hematogenous spread. Even the mandible which is so close to the most frequent site of actinomycosis, the cervicofacial region, is rarely invaded by direct extension (Kaufmann²¹). The spine is the most common of the bones affected. There are sharply defined abscesses, as a rule present in two or more vertebrae. The bodies, pedicles, and laminae are attacked, but the intervertebral discs are usually spared. A marked destruction of the vertebral bodies may occur without collapse or kyphosis (Tabb and Tucker²²).

It is beyond the scope of this paper to discuss at any length the varied and bizarre symptoms that can occur in a pyemic disease of this kind. The symptomatology will, of course, depend upon the organs affected and the extent of disease in these organs. Before generalization has occurred the symptoms are those of the primary lesion. If it be in the lung, as it usually is in these cases, then the severity of the symptoms will usually be proportional to the extent of the lesion. Cough and expectoration of sputum which is occasionally blood streaked are prominent complaints. Pain in the chest, night sweats, fever, and loss of weight are not unusual. The sputum may be thick, copious, and fetid, or it may be scanty and odorless (Christison and Warwick²³). Once generalization has occurred, the symptoms referable to other organs affected may be so prominent that they completely overshadow those of the primary lesion and one has to question the patient carefully to learn the nature of the onset of the illness.

The temperature is hectic, usually ranging between 98 and 102 degrees. The pulse rate is proportional unless there is cerebral involvement with increased intracranial pressure. Chills and sweats are frequent. The white blood cell count ranged between 10,400 and 19,600 in those cases in which it was reported.

The differential counts showed between 82 and 88 per cent polymorphonuclear leukocytes and 12 to 18 per cent lymphocytes. Moderate secondary anemia is usually present.

Perhaps the most important factor in the diagnosis is to remember that this disease, although extremely rare, does exist. It should be considered in all pyemias whose origin and nature are not apparent. The duration of the entire illness in the cases reviewed ranged between three months and two years. However, it was not always possible to determine from the histories given approximately when generalization had occurred. It is likely that most patients live but a few months after metastases are evident.

A careful search of the sputum should be made when the disease is suspected. If sulfur granules are present and these, on microscopic examination, show the mycelia, the diagnosis is definite. It is not sufficient to culture a routine sputum specimen for fungi. As was mentioned before, actinomyces have been found in the mouths of normal individuals, and a positive culture may readily lead to error.

A careful examination of pus obtained from secondary foci may lead to the diagnosis as it did in our case. This, of course, is not always possible. Biopsy examination is indicated whenever it can be done. Blood cultures have been almost uniformly negative. Fellingner and Salzer¹⁰ obtained a culture from the postmortem blood which was pathogenic for laboratory animals. Freed and Light⁹ claim that they obtained four aerobic cultures in their case during life, but no attempt was made to produce the disease in animals.

Attempts have been made to develop an intradermal reaction as a diagnostic test in actinomycosis, but the results thus far have been controversial and discouraging. De Area-Leao²⁴ reported distinct cutaneous reactions in two cases of actinomycosis when 0.3 c.c. of a filtrate from an old broth culture of *actinomyces bovis* was injected intradermally. Normal individuals gave no reaction to such injections, and control injections of sterile broth also failed to give positive results. Adant and Spehl²⁵ also obtained positive intradermal reactions in two cases of pleuro-pulmonary actinomycosis by using a filtrate of an old culture of *actinomyces bovis*. The reaction appeared 12 hours after injection, was characterized by erythema, an indurated zone 2 to 3 cm. in diameter, and disappeared in four or five days. They also obtained negative results in normal individuals, but did observe positive reactions in patients having other types of mycotic infections. They concluded that a positive reaction was indicative of a mycotic process in the body, but was not specific for actinomycosis. On the other hand, Mathieson, Harrison, Hammond, and Henrici²⁶ found that normal individuals gave more frequent and more marked skin tests to *actinomyces bovis* than did actinomycotic patients.

SUMMARY AND CONCLUSIONS

A case of the generalized form of actinomycosis has been presented. The primary lesion is, in most instances, in the lung. Metastases may be wide spread or few in number. The brain is the most frequent organ secondarily involved. The symptoms are varied depending upon the organs affected.

ABNORMAL SENSITIVITY TO LIGHT IN A CASE OF POSSIBLE LANDRY'S PARALYSIS¹

By H F BLUM and I C SCHUMACHER, F A C P, *Berkeley, California*

THE purpose of this report is to describe a condition of acute hypersensitivity to light occurring in a patient during the earlier stages of a fatal ascending paralysis resembling the type described as Landry's syndrome, and to discuss the relationship of this condition to other types of photosensitivity. The patient remained in the hospital for a period of two weeks, during which time it was possible to make a rough characterization of her sensitivity to light. No definite diagnosis of her condition was made at the time, although certain neurological changes were observed. A few days after returning to her home in a nearby city, acute dementia and marked paralysis—first of the feet, then of the legs, and on up—developed, and she died on February 17, 1935. No autopsy was performed, but the clinical diagnosis made by the attending physician was Landry's paralysis.

When first observed in the hospital, the patient displayed a fiery erythematous dermatitis on the face, hands and arms. The delimitation of this dermatitis was such as to suggest that it was the result of exposure to light, only the face, hands and arms were affected and these only on the parts which would be most exposed to sunlight. The submental triangle, and the interior surfaces of the hands and arms which would ordinarily be shielded from light showed little or none of the erythema. A very striking demarcation existed between the erythematous exterior surfaces of the hands and arms, and the more or less normal medial surfaces, this is shown in the photograph reproduced as figure 1, which was taken after the patient had been in the hospital for two weeks protected from direct sunlight, and the erythema had begun to fade. The dermatitis was more noticeable on the lower arms and the hands than on the upper arms, as though the periods of exposure had been different due to the wearing of different sleeve lengths. No trace of the dermatitis appeared on any portion of the body which might not have been exposed to light under ordinary circumstances. The answers of the patient to questions regarding exposure to sun were not trustworthy, at one time she denied having been recently exposed directly to sunlight, but at other times stated that she had been so exposed. The following is a summary of the history, physical, and laboratory findings other than sensitivity to light.

CASE REPORT

G K, a 40-year-old white American housewife, was admitted to the University of California Hospital on January 6, 1935.

Chief Complaints Swelling of the face, with a burning, itching eruption of the face, hands and arms, progressive weakness, and vomiting.

Family History The maternal grandfather died of cardiac disease, and the maternal grandmother of renal disease. No history of tuberculosis in the family was obtained.

* Received for publication March 1, 1937.

From the Division of Physiology and the Division of Medicine of the University of California Medical School.

Assisted by a grant from the Research Funds of the University of California.

FIG 1

Marital History The patient had been married for 21 years. Her husband was living and well, age 41. Two children, ages 7 and 19 respectively, were living and well. There had been no miscarriages or abortions.

Past History The patient had pneumonia at the age of 12, and again when she was 39 years old. She had scarlet fever when she was 21 years old, and at the same age, when her first child was born, she was confined to bed for several weeks with fever, pleurisy and hemoptysis. Tonsillectomy and appendectomy were performed at the age of 28. At the age of 30, she was confined to bed for two months because of shortness of breath and tachycardia. Cholecystectomy was performed when she was 28 years old, for cholecystitis and cholelithiasis, recovery was uncomplicated.

Menstrual history was negative except for two periods missed between October and December 1934.

The patient has been obese since the age of 27, average weight, 225 pounds. Her weight reached a maximum of 250 pounds when she was 34 years old. At the time of admission to the hospital she weighed 216 pounds.

Present illness began with a sore throat and fever in October 1934, three months prior to entry. This was followed in two days by generalized muscular tenderness and soreness. The patient went to bed, and remained in bed until she entered the hospital. A week after the onset of illness she was seen by the family physician, and quinine in capsules was prescribed. Several days later, after she had taken 12 of these, an eruption appeared—first on the cheeks, then on the hands, arms and legs, and eventually over the entire body. This eruption consisted of minute red areas, which later coalesced to form purpuric patches. The quinine was discontinued, and sodium salicylate was given by mouth. Her fever gradually subsided. Marked swelling of the face with brawny induration appeared, later extending to the dorsum of the hands and forearms.

After one month the brawny induration and eruption of the skin had disappeared except that of the face, an exposed area of the chest not covered by her nightgown, and the extensor surfaces of the hands and fingers. These areas felt hot to touch, although the patient had no fever at this time. Parts of the skin not exposed to light showed no discoloration. One month after the onset of illness, heavy traces of albumin appeared in the urine, and were present there for one month during which time the patient's legs and forearms were quite noticeably swollen. This edema subsided as the albuminuria disappeared.

Shortly after the onset of her illness, the patient noticed weakness of the extremities, especially of the legs. This weakness progressed until, at the time of entry into the hospital, she was unable to rise from a sitting position.

Six weeks prior to entry, the patient began to have attacks of vomiting, which occurred usually in the mornings after breakfast, later, though not frequently, at other times of the day. Her appetite became poor, but loss in weight was slight. A study of her dietary habits previous to her present illness revealed no outstanding deficiency. During her illness previous to entry, her diet had consisted mainly of citrus fruits with the occasional addition of toast and cereal. For three weeks before entry, all medication was withheld without causing relief of her symptoms, and darkening of the patient's bedroom had no appreciable effect on the skin lesions.

Physical examination showed an obese woman, lying in bed in no apparent distress. The appearance of the skin has been described elsewhere. The heart and lungs were negative. Pulse was regular in force, rhythm 120 per minute. Blood pressure with the patient prone was 150 mm of mercury systolic, and 95 mm diastolic. The abdomen was very obese, and covered with numerous striae. An upper right rectus scar was present, and an old appendectomy scar. No abdominal organs or masses could be palpated. Pelvic examination showed an irregular, torn cervix, and the presence of a leukorrheal discharge. Rectal examination was negative. There was muscular weakness in all extremities, and the muscles were flabby. Arm reflexes were present but hypoactive. Knee jerks could not be obtained. Ankle jerks were present. Plantar response was normal. There was reduced sensitivity to pinprick over the medial aspects of both legs from the knee to the ankle, as well as over both deltoid regions and the upper outer chest. The reactions to heat, cold and vibration were normal.

Laboratory Tests

Urine Dark brown to brick-red in color, acid, sp gr 1.030 to 1.041. Albumin faintest possible trace, to negative. Reducing bodies absent. Acetone negative. Sediment (uncatheterized specimen) showed 20 pus cells per high dry field, no casts, no red blood cells. Spectroscopic test for hematuria negative.

Stool No occult blood, no parasites.

Blood Hemoglobin (Sahli) 85 per cent (12.3 gm), red blood cells 4.05 to 4.65 million per cu mm, white blood cells 7,200 to 5,550 per cu mm. Differential count: PMN 58 to 70 per cent, PME 0 to 5 per cent, PMB 0 to 1 per cent, lymphocytes 20 to 21 per cent, and monocytes 20 to 16 per cent. The red blood cells showed slight microcytosis and poikilocytosis. Platelets appeared normal in number.

Blood Kahn and Kolmer quantitative test negative. Non-protein nitrogen 30.8 mg per cent. Creatinine 1.3 mg per cent.

Gastric analysis Free hydrochloric acid present.

Basal metabolic rate Plus 24 per cent (probably inaccurate as patient was restless and uncooperative).

Tuberculin skin test Negative to 1 cc of 1:1000 human.

Electrocardiogram (interpreted by Dr. Wm. J. Kerr) showed a rate of 103 per minute, regular rhythm, left ventricular preponderance, slurred QRS complexes.

Roentgen-ray examination of the chest (by Dr R S Stone)—films and fluoroscopy The heart appeared to be enlarged transversely The lungs appeared clear The spleen could not be seen under the fluoroscope

Course The patient was placed on a diet of 1,200 calories Sodium amytal and later chloral hydrate were administered for sleeplessness Massage and passive exercise of all extremities were given During the first four days there were slight daily elevations in temperature, the highest being to 37.7°C on the day of entry, throughout the remainder of her stay in the hospital, the patient's temperature was usually normal, occasionally rising to 37.5°C Her pulse varied between 80 and 120 per minute Vomiting occurred on only a few occasions, chiefly when she was disturbed by diagnostic procedures

Throughout her stay in the hospital, no apparent change occurred in the patient's general condition She remained irritable and uncooperative, and was somewhat resistant to all examinations Details of the diagnostic studies made to determine the etiology of the skin lesions are described below The patient was discharged from the hospital on January 23, 1935

Subsequent course The following information was received from her family physician "About four or five days after returning home, the patient began to complain of increasing weakness in both limbs below the knees, together with recurrent attacks of vomiting A flaccid paralysis set in, involving first the feet, then the legs, thighs, body muscles, upper extremities, and finally the muscles of deglutition The patient became delirious, her temperature rose rapidly, and she died on February 17, 1935 No autopsy was obtained

"At no time did she complain of any pain, there were no convulsive seizures or muscle spasms, nor was there any incontinence, urinary or fecal

"The diagnosis made by the consulting neurologist was Landry's ascending paralysis"

EXPERIMENTAL

Reproduction of the Lesions by Quartz-Mercury Arc Radiation On a number of occasions small areas of the skin of the thighs were subjected to the radiation from a quartz-mercury arc in doses which were estimated as capable of producing only a very mild erythema in normal skin The patient always responded to this treatment with erythema much more severe, and much more persistent than that produced in normal individuals by similar doses, and in the course of a few days the irradiated areas developed the appearance of the erythematous dermatitis which covered her face, arms and hands We will describe a single controlled experiment An area of the skin of the thigh, about 5 cm square, was exposed to the radiation from a quartz-mercury arc of the Hanovia Alpine Sun type, for a period of three minutes at a distance of 20 inches To serve as a control, a light complexioned, healthy individual was given a like exposure, at the same time Within a few hours the normal individual developed a very mild erythema of the irradiated area, which faded in the course of the following day and on the second day could be no longer detected The patient developed an erythema at about the same time as the control, but which, in contrast, increased in intensity for several days On the second day following the irradiation the patient showed a bright red erythema of the irradiated area, at which time the control exhibited no further traces of reaction to the exposure Three days later the exposed area was still bright red and showed a slight scaling, it resembled very closely the erythematous dermatitis exhibited by the face and arms This erythema persisted until the patient

left the hospital 11 days following the irradiation, at which time it was beginning to fade. Another area irradiated two days previous to the above still showed erythema at the end of 13 days, and was beginning to exhibit definite signs of pigmentation at that time.

One area which was given a number of successive irradiations developed a somewhat less severe erythema than the others. The explanation of this is difficult, but it is possible, since this experiment was performed somewhat later than any of the others, that the patient's sensitivity was beginning to decline.

We feel that in these experiments we have reproduced the lesions which this patient displayed on entering the hospital by relatively mild exposure to quartz-mercury arc radiation, her response to such radiation being much more severe and persistent than that of normal individuals.

Delimitation of the Wave Lengths Producing the Erythema The importance of determining what wave lengths produce abnormal sensitivity to light has been stressed elsewhere by the writer (Blum, 1933, Blum et al., 1935). Such a study provides the possibility of deciding whether the abnormal sensitivity is due to a hyperactivity of the normal photodermal mechanism, or is due to the activity of an abnormal photosensitizing substance as is the case in *vitiligo solare* (see Blum, Allington and West, 1935). To determine which part of the mercury arc spectrum was active in producing the erythematous reaction described above, we exposed five areas on the thigh simultaneously to the same dose of quartz-mercury arc radiation used in the experiment described above, one of these areas was exposed directly to the full radiation of the arc, while the other four were covered by glass filters of different spectral transmissions (774, W G, 385, 038, figure 2). A severe erythema of the type described above developed on the area exposed directly to the arc, but no changes were detected on any of the areas covered by the filters. On a later occasion fresh areas were covered with the filters and exposed to the arc for a period of 15 minutes, but again no changes were observed, an exposure of this duration to the direct arc should produce a severe burn in a normal individual.

The curve N E in figure 2 shows the relative effectiveness of various wave lengths in eliciting erythematous response from normal skin, from which it will be seen that no wave lengths greater than 3200 Å are effective. The filter transmissions are also shown in this figure, and it will be seen that any of the filters used above (774, W G, 385, 038), which prevented the production of the abnormal erythematous response in our patient, will also prevent the production of erythema in normal skin, since all remove the radiation shorter than 3200 Å, except 774 which permits only a very slight fraction of the erythemal radiation to pass. On another occasion an area was irradiated through filter 970 for a period of three minutes, with the result that a milder erythema developed than that produced by the full arc although more severe than that which would be elicited from normal skin by such a dose. Figure 2 shows that this filter permits only a part of the normal erythemal radiation to pass, so that the effectiveness of the dose should be considerably decreased.

These experimental facts lead to the conclusion that the wave lengths which produce the abnormal erythematous response in our patient are the same as those which produce erythema in normal individuals. While we cannot rule out the possibility of an abnormal photosensitizing substance having its ab-

sorption spectrum in the same region as that of the substance responsible for normal erythema, it would seem reasonable to neglect this rather vague hypothesis and assume that the abnormal sensitivity of our patient represents a hyperactivity of some part of the normal photodermal mechanism

A much more careful analysis of the spectral sensitivity would be required to give complete justification to this last assumption, but such an analysis would require considerable time and equipment and would not be feasible as a rule when such cases come to observation. On the other hand, the equipment used in the above experiments should be available in any hospital. If a set of filters of known spectral transmissions is not at hand a great deal may be learned by

FIG 2

Abscissa—wave lengths in Angstrom units

Ordinates—arbitrary values

NE—normal erythemic response (after Coblenz and Stair, 1934)

H—absorption of hematoporphyrin (values of ϵ calculated from Clar and Haurowitz, 1933)

970, 774, 385, 038—transmissions of Corning glass filters characterized by these numbers
W G—transmission of a window glass filter. The broken line represents 100 per cent transmission of the filters. The transmission of filter 038 was determined by means of a spectrophotometer, the transmission of the other filters was determined by means of a quartz spectrograph

Vertical lines—the principal emission lines of the quartz-mercury are in this region. The height of the line is proportional to the intensity (data from McAlister, 1933, for a quartz-mercury arc operated at 150 V, 45 A)

using a single filter consisting of a piece of ordinary window glass. The common window glass which appears green when viewed edge on is of fairly uniform spectral transmittency, cutting off the shorter wave lengths at approximately the point where the photo-sensitivity of normal skin ends, i.e., about 3200 Å (see figure 2). If the lesions may be reproduced by radiations passing through window glass, an abnormal photosensitizer may be assumed to be present. If, as in the present case, the patient is hypersensitive to direct quartz-mercury arc radiation but not to that part of such radiation which passes through window glass a hypersensitivity of the normal photodermal mechanism is probably involved. If window glass or any other filters are used in such tests their spectral transmission should be carefully determined. This may be very

well accomplished after the completion of the experiments, as happens to have been done in the present case, thus no time need be lost in making the observations

Since in the present study the lesions were reproduced by quartz-mercury arc radiation, it did not appear important to examine carefully the effects of the spectrum not emitted by this source, the principal lines of which are shown in figure 2 (only a part of the visible spectrum is shown in the figure, the remainder being of no particular interest to the present study) However, an area of the patient's back was exposed to direct sunlight for a period of 20 minutes on one occasion, but without eliciting any skin changes Sunlight does not as a rule contain enough radiation shorter than 3200 Å to produce erythema in normal skin in this period of time, but the quantity of nearer ultraviolet and visible radiation is many times greater than that obtained from the mercury arc

All of the experimental results are summarized in table 1

TABLE I

| Source | Exposure time | Filter | Wave lengths transmitted by filter† | Response |
|---------------------|---------------|--------------|-------------------------------------|------------------|
| Quartz-mercury arc* | 3 min | None | All | Severe erythema‡ |
| " " " | 3 min | 970 | 2600 and longer | Mild erythema |

† Only wave lengths in the ultraviolet and visible are considered

‡ Subsequently developing into an erythematous dermatitis persisting for several days

DISCUSSION

Naturally occurring porphyrins are under suspicion as photosensitizers in man In fact, this suspicion seems to have crystallized into the belief that porphyrins are *the* sensitizers in all cases of photosensitivity, and statements to this effect are quite common We cannot find space here to discuss the origin of this idea, but only to say that the status of porphyrins as sensitizers in abnormal light sensitivity is not completely understood

It will be of interest to consider the possible relation of porphyrin to the present case Landry's syndrome is an ascending paralysis which, according to Drake (1935), may have either a toxic or an infectious background, it does not appear to be a single disease entity In a certain number of such cases porphyrin appears in the urine (see Mason et al, 1933), and there is reason to think that it would be more often found if careful search were made Although we did not demonstrate porphyrinuria in our case, there is no reason to believe that porphyrin or porphyrinogen might not have been found if more and larger urine samples had been examined Had we found porphyrin, we might have placed this case together with those of Mason, particularly since the patient was a woman, and 90 per cent of the cases of Landry's paralysis with porphyrinuria

are women (Mason et al, 1933) Porphyrin is found associated with a certain proportion of cases of *Hydroa Vacciniforme seu Aestivale* (17.5 per cent according to an analysis by Senear and Fink, 1923), which is a condition of abnormal sensitivity to light resulting in severe and often disfiguring lesions of the exposed parts. It has also been found in other cases of photosensitivity displaying other kinds of lesions (Barber, Howitt and Knott, 1926, Goekerman, Osterberg and Sheard, 1929). Furthermore, it has been demonstrated that porphyrins are photosensitizers for a wide variety of living systems (see Blum, 1932 or 1935, for an account of this type of photosensitization). Meyer-Betz (1913) produced general photosensitization in himself by the injection of a rather large dose of hematoporphyrin, and Duke (1923), Frei (1926), and Blum, Watrous and West (1935) produced local photosensitivity in human skin by the intradermal injection of this pigment. After a brief consideration of this evidence, one might seem justified in jumping to the conclusion that the sensitivity to light in the present case is the result of the presence of a porphyrin acting as a photosensitizer. In fact, this exact line of reasoning has been often followed. However, there is a very strong case against porphyrin as a sensitizer in the present instance, and we should probably find the same to be true of many others if the proper experimental evidence had been obtained. For this reason, we will consider the opposing evidence at some length.

In order for a substance to act as a photosensitizer it must absorb radiation, and it can only absorb those wave lengths which fall within its characteristic absorption spectrum. Thus the absorption spectrum of a substance should show approximately the wave length region in which it may act as a sensitizer*. While the porphyrins differ in the finer structure of their absorption in the visible region they all show a strong absorption just at the borderline between visible and ultraviolet, with a maximum at about 4000 Å. This absorption falls off to minima at about 3000 Å on the ultraviolet side, and at about 4500 Å on the visible side. Examination of the data of Hausmann and Krumpel (1927), and of Clar and Haurowitz (1933), will show the similarity of the absorption spectra of the different porphyrins in this region and that it is not greatly affected by the solvent. The spectra in the visible region vary much more for the different porphyrins, but according to the data of Clar and Haurowitz the visible absorption is very much less than that in the ultraviolet. The data of Hausmann and Krumpel would indicate a much greater absorption in the visible, but it is probable that no correction for the characteristics of their photographic plates was made in preparing their figure, so that their measurements are not quantitatively correct. Their data are nevertheless valuable in giving a comparison of the approximate positions of the absorptions of a number of different porphyrins.

The absorption spectrum of a typical porphyrin in the ultraviolet region is shown in figure 2, and it may be seen at a glance that there is no agreement between this curve and the sensitivity of our patient. In fact, our patient was sensitive in a region at which a minimum in the absorption spectrum of hematoporphyrin occurs. Furthermore, the experiments of Hausmann and Sonne (1927) and of Hausmann and Kuen (1933) on the sensitization of erythrocytes by porphyrins also demonstrate experimentally that these substances do not sensitize in the region of the normal erythemal response, with the exception of

* A corollary of the Grotthus-Draper law, the first law of photochemistry.

mesoporphyrin, which may show some sensitizing effect in this region, but also exhibits very strong sensitization in the nearer ultraviolet and visible (Hausmann and Kuen). We have found that when the skin is sensitized locally by intradermal injection of hematoporphyrin, the response to sunlight is of the same magnitude when a filter of window glass is interposed as when exposed directly to the sun. Thus all the evidence points to the fact that the wave lengths to which porphyrins sensitize do not correspond at all with those to which our patient was sensitive.

It was suggested that the sensitization might be the result of the quinine which was given the patient some time before she entered the hospital, and to which she responded with a marked dermatitis, not, however, limited to the exposed parts as was the later dermatitis which we observed. Quinine has been stated to be a photodynamic photosensitizer by some investigators, but Frei (1926) was unable to obtain sensitization of the skin to sunlight by the intradermal injection of this drug. The absorption spectrum of quinine (Hicks, 1930, Heidt and Forbes, 1933) indicates a very considerable absorption of radiation between 3000 Å and 4000 Å, the absorption shorter than 3200 Å is considerable, but if one examines the transmittance of skin as shown in the curves of Bachem and Reed (1931) one finds that the transparency of the epidermis falls off very rapidly below 3500 Å which would tend to limit the sensitizing power of quinine in the region to which our patient demonstrated her greatest sensitivity, i.e., below 3200 Å. From a consideration of these data it appears that if quinine were the sensitizer in the present case, the patient should react to radiation much longer than that to which she is sensitive, and should be more sensitive to radiation longer than 3200 Å, than to radiation shorter than this limit. Thus, if quinine was an etiological factor in the sensitivity of the skin to light it must have acted to enhance some part of the normal photosensitive mechanism, not as a specific photosensitizing substance in the skin.

The response of normal skin to light must be rather complex. There must be first a photochemical reaction, the products of which bring about dilation of the small vessels in the skin, which is observed as erythema, and subsequently pigmentation. The steps involved may be even more numerous, and we must assume that there are a number of parts in the whole system, the hyperactivity of any one of which might result in an enhanced erythemic response. Thus it is not surprising to find that a profound and general nervous disturbance of the type occurring in our patient should be accompanied by a sensitivity to light as the normal erythemic mechanism must be affected by any disturbance in the control of the minute vessels, nor again where the administration of a drug produced marked skin changes. Such an enhanced response would, of course be produced by the same wave lengths as the normal response, and it is probable that many cases of abnormal sensitivity to light are of this type. The group of individuals ("vegetativ Stigmatisierten") whom Ellinger (1932) found to show a greater sensitivity to quartz-mercury arc radiation than normals, may probably be placed in this group. He believes this condition to be associated with thyroid gland disturbance. We see no reason, however, for believing that the thyroid gland is directly involved in the photosensitivity of our patient, but the possibility cannot be excluded. On the other hand, a number of cases have been reported in which the sensitivity lies in a wave length region outside of the normal and in which an abnormal sensitizer must be present. The cases of

Urticaria solari described by Duke (1923), Vallery-Radot et al (1926, 1928), Frei (1925), and Blum, Allington and West (1935) offer examples of the latter type, as does also the condition described by Urbach and Konrad (1929), and in all probability there are others. The position of Hydroa would seem to be questionable (see Gottron and Ellinger, 1931) and it may well be that the etiology is not the same in all the cases described under this name. Conditions involving abnormal sensitivity to light can be properly characterized only when wave length studies are carried out and it is to be hoped that these will be more frequently made in the future than in the past. We may point out that the same treatment would hardly be expected to succeed in cases of all types.

SUMMARY

1 A condition of abnormal sensitivity to light in a case of ascending paralysis, manifesting itself as an erythematous dermatitis on the face, hands and arms, is described.

2 Quartz-mercury arc radiation produced a much more severe, and persistent erythema in the skin of this patient than in normal skin, and this took on the appearance of the erythematous dermatitis displayed by the patient.

3 Only that portion of the mercury arc radiation shorter than 3200 Å was active in eliciting this erythema. The sensitivity would thus seem to be restricted to the same wave length region as the erythematous response of normal skin, and the condition could best be explained as a hypersensitivity of some part of this mechanism.

4 It is pointed out that porphyrins or quinine cannot be suspected as photosensitizers responsible for this condition.

5 The relationship to other types of photosensitivity is discussed.

EDITORIAL

ADRENAL ATROPHY AS A CAUSE OF ADDISON'S DISEASE

Various pathologists^{1,2} have drawn attention recently to the increasing frequency with which adrenal atrophy is found as the causative lesion in Addison's disease. It was formerly estimated that atrophy was found in only about 10 per cent of the autopsies of cases of Addison's disease and tuberculosis of the adrenals in the other 90 per cent. However in recent years, as pointed out by Wells,¹ series of cases have been reported in which atrophy was found in as high as from 30 to 50 per cent of the instances.

In Brenner's review of the subject he pointed out the chief features of adrenal atrophy. It is a non-inflammatory process, including necrosis of either the adrenal cortex alone or of the cortex and medulla, followed by a disappearance of the necrotic tissue with a corresponding shrinkage of the adrenal. Ineffective regenerative changes are observed. In the type most commonly found associated with Addison's disease it is the cortical zone which has largely disappeared leaving the medulla relatively intact.

Since in the type of tuberculosis of the adrenal which is found as a cause of Addison's disease both the cortex and the medulla are usually destroyed, it might be supposed that clinical distinctions would be found to correspond with these variations in the tissue involvement accompanying these two etiologic types of Addison's disease. Wells raises the question whether longer duration and a less pronounced hypotension may not characterize the cases due to purely cortical deficiency. The matter is, however, by no means definitely settled.

The nature of the process which results in the necrosis of the adrenal cortex, with or without some medullary damage, is still quite undetermined. It is well known, however, that in experimental animals the adrenal cortex is very susceptible to bacterial toxins such as diphtheria toxin and also that human cortical tissue will show evidence of damage in all cases that have died as a result of acute infections. Basic studies establishing this fact were those of Dietrich³ during the World War. This investigator utilized the opportunities of examining healthy human glands from those who had met sudden death. With these he compared the glands removed from a series of cases in whom wound infection was the cause of death. The cortical tissue in these latter uniformly showed destructive changes.

Such cortical damage in infectious diseases is probably repaired rapidly as a rule since the cortical cells and especially those of the *zona glomerulosa* are capable of rapid regeneration. Such regeneration is readily observed in

³ DIETRICH, A. Die Nebennieren bei den Wundinfektionskrankheiten, Centralbl allg Path, 1918, 11, 169.

experimental animals. How frequently residual atrophy remains is not known.

In certain dramatic instances the damage to the adrenal in infections consists of massive hemorrhage with disintegration of the glands. These cases are marked by skin hemorrhages, vasomotor collapse and early death. The syndrome is associated especially with the onset of meningococcus infections, less frequently with those due to the pneumococcus.

No conclusive study in humans has yet shown how large a part in the clinical phenomena of acute infections may be played by less extensive forms of damage to adrenal cortical tissue. It might well be of course that such damage might result in a mingling of symptoms of acute adrenal insufficiency with those due to the other results of the infection. Moreover, besides this obvious possibility, it must be recalled that the adrenal bears some relation to bodily resistance to infection the nature of which is by no means clear. Both adrenalectomized animal and human cases of Addison's disease become abnormally susceptible to the effects of infections, and to the action of bacterial toxins and of certain poisons. Moreover it seems possible that the adrenal cortex as a storage place of cevitamic acid, which has been shown to be capable of stimulating antibody formation, plays still another rôle in connection with the bodies' response to acute infectious disease.

Susman has raised the question whether repeated past infections or poisonings may not account for the multiple atrophic spots he has noted in the adrenal cortex of some autopsy cases and suggests that possibly in susceptible individuals, more extensive damage of this kind might eventually lead to such complete cortical atrophy as would cause Addison's disease.

Another explanation of chronic cortical atrophy has appealed to Wells.⁴ He has several times drawn attention to the similarity between the pathologic cellular necrosis in cortical atrophy and that which is seen in acute yellow atrophy of the liver. Both, Wells feels, are best described as toxic cellular necrosis. Wells is inclined to carry the parallelism further and to suggest that, just as the increase of acute yellow atrophy was probably attributable to poisons such as cinchophen, so there might also be found a poison responsible for the apparent increase in the number of cases of adrenal cortical atrophy. Recently Wells encountered a case of cortical atrophy probably due to the therapeutic use of *germann* and was able to show that this drug has a fairly specific damaging effect upon the adrenal cortex of laboratory animals.

It seems apparent that this suggestion is one which clinicians should bear in mind in investigating the history of patients with Addison's disease.

REVIEWS

Bright's Disease and Arterial Hypertension By WILLARD J STONE, B Sc, M D, F A C P, Clinical Professor of Medicine, University of Southern California 352 pages, 16.5 × 24 cm W B Saunders Co, Philadelphia 1936 Price, \$5.00

This volume opens with brief historical sketches of those whose names have been associated with studies in the field of renal disease. Then follow chapters on classification of renal disease (the author presents a modification of the classification of Volhard and Fahr), renal physiology, water balance, edema, renal function tests, uremia, etc. These chapters constitute too briefly stated reviews of the more prevalently accepted current theories. There is little or no critical discussion and the author offers little in the way of personal opinion. Subsequent chapters deal with "Acute Hemorrhagic Bright's Disease, Second Stage Hemorrhagic Bright's Disease, Terminal Stage Hemorrhagic Bright's Disease, Acute and Chronic Degenerative Bright's Disease." Forty-four pages are devoted to arterial hypertension, arteriosclerosis and arteriosclerotic Bright's disease. This latter subject is divided into latent and active forms by the author. The second part of the title seems scarcely justified by the amount of discussion given it as such. The 140 autopsied cases of Bright's disease are abstracted too briefly to be very instructive.

W S L, JR

Dextrose Therapy in Everyday Practice By E MARTIN, Sc D 451 pages, 16 × 24 cm Paul B Hoeber, Inc, New York 1937 Price, \$3.00

An impersonal digest of significant dextrose literature since 1900, this readable book correlates experimental laboratory and clinical findings with admirable brevity. More than a handbook, it succeeds in giving a dextrose-eye view of metabolism without losing yardage in controversy or flight of fancy. The first portions dealing with chemistry and physiology show occasional proof-reader's errors (*normal blood sugar range is from 0.8 to 0.12*) which tend to shake faith in figures quoted which are less familiar. The author is strict enough too in insisting on the substitution of chemically correct *dextrose* for the familiar *glucose* of common parlance. Yet later on he uses *glycolysis* where *glycogenolysis* is apparently meant. The latter portions of the book show the difficulty of the pure-scientist-in-medicine's uncritical acceptance of medical literature at its face value (as where on p. 110 he so glibly speaks of *simple blockage of the reticuloendothelial system*). His therapy has a Gould and Pyle-ishness throughout that is most dangerous in the genito-urinary section where he is still in the intravenous mercurochrome era. The charts are good, and the pictures better than average. Definitely a transition book, it would interest the clinically-minded second-year, and the chemically-minded third-year medical student, and be helpful provided that the student remembers that dextrose is but one of many therapeutic agents.

C A

Gastrosocopy The Endoscopic Study of Gastric Pathology By RUDOLF SCHINDLER, M D 343 pages, 17.5 × 25 cm University of Chicago Press, Chicago, Ill 1937 Price, \$7.50

Every chapter in the book is full of valuable information. The technic of gastrosocopy is clearly and concisely stated. The splendid description of the procedure will be extremely helpful to those who desire to do gastrosocopy. To those not desir-

ing to do gastroscopy, it will materially broaden their knowledge of the technical side of the procedure. When technical problems do occur, they are comparatively easy to overcome if one follows the directions as outlined in the chapter on technic. The reviewer has followed very closely the technic as outlined, and has found it most satisfactory. The position of the patient for emptying the stomach is of the utmost importance, and this has been stressed by the author. Likewise, the orientation of the instrument in the stomach has been described thoroughly. This, of course, is very necessary, so as to be able at all times to know which portion of the stomach is being observed.

Many diagrams have been used to show the portion of the stomach visualized, with the instrument at different levels, and when the instrument is rotated in different positions. Great detail concerning orientation is of the utmost importance. The technic of introducing the gastroscope can be mastered in a very short time, but to be able to determine accurately the portion of the stomach under observation, requires a great deal of training. The gastroscopic appearance of the normal stomach is extremely well presented. After all, one must be perfectly familiar with the picture of the normal stomach before attempting to study gastric pathology.

In the study of gastric pathology, the author stresses two important diagnostic procedures, namely roentgen-ray relief studies, and gastroscopy. Both have a definite place in the diagnosis of gastric lesions. The two methods bear a supplementary relation to each other. Certain facts may be obtained by one procedure, and other very definite facts obtained by the other.

The author definitely favors gastroscopy in studying the different types of gastritis. His classification of the different types of gastritis is all that can be desired, the different types are easily recognized gastroscopically. In the diagnosis and treatment of gastric ulcer, the author stresses the importance of gastroscopy, and urges the advantage of frequent gastroscopic examinations to determine what results are being obtained from treatment. In the diagnosis of carcinoma, he believes a positive diagnosis can be made by roentgen-ray relief studies and gastroscopy. He does not believe there is any necessity for surgical exploration of the abdomen in any case in order to make the diagnosis. He makes a strong plea for roentgen-ray relief study and thorough gastroscopic examination, and states that the two methods of examination will give one the correct diagnosis in almost every case. The reviewer believes that in order to make the diagnosis of carcinoma by these two methods alone, one must have had a vast amount of experience in gastroscopy, and in the interpretation of roentgen-ray relief studies. In determining the etiology of obscure gastric hemorrhage, the great advantages of gastroscopy have been thoroughly discussed.

In addition to the clear and concise manner in which gastroscopy has been discussed, the book contains a very complete bibliography of the subject, and 96 perfectly splendid color plates. One not familiar with gastroscopy might be inclined to doubt the brilliant colors found in the plates. The reviewer, however, from his own experience, believes that the colors are not exaggerated, but quite clearly represent different phases of gastric pathology. With each color plate, there is a short discussion of what it represents.

The book should be of real value to every internist, and especially to those limiting their practice to gastroenterology. It is of course, of the utmost value to those interested in gastroscopy. The reviewer is of the opinion that gastroscopy as a diagnostic procedure is just as valuable as the roentgen-ray, in the diagnosis of gastric pathology. It in no way replaces roentgen-ray studies—they both bear a supplementary relation to each other.

E B F

Endocrinology Clinical Application and Treatment By AUGUST A. WERNER, M.D., F.A.C.P. 672 pages, 15 × 24 cm Lea and Febiger, Philadelphia 1937 Price, \$8.50

Quite a number of texts on endocrinology have been published within the past few years. On greeting a new publication one is interested to see how it differs from, or what it adds to, those already available.

This particular work contains many valuable data amassed from the author's large practice and wide experience. There are many case reports and many illustrations. The classical endocrine syndromes are well delineated.

In the opinion of the reviewer, the book is marred somewhat by the enthusiastic inclusion of many conditions of unknown origin as of probable or possible endocrine etiology.

The illustrations in general are excellent but there are included some of questionable choice, notably that illustrating lipodystrophia progressiva, a very good photograph of a very fat woman but lacking the essential characteristic of this rare anomaly, namely, the remarkably complete emaciation above the waist.

The book gives a good idea of the methods of practice of an enthusiastic and well informed endocrinologist.

T P S

The Digestive Tract A Radiological Study of Its Anatomy, Physiology and Pathology By ALFRED E. BARCLAY 427 pages, 19 × 25 cm Cambridge University Press Department, Macmillan Co., New York 1937 Price, \$12.00

A striking feature of this book is that the author obviously considers an understanding of the normal, an essential prerequisite to the evaluation of pathological change, since he devotes roughly the first half of his book to anatomy and physiology from the point of view of the radiologist. Included in this discussion are summaries of some of the latest researches on the digestive tract.

The book is divided into three main parts. Part I is devoted to technic including not only a careful review of routine measures employed in the practice of radiology but also stressing some of the dangers associated with this work. The completeness and the clarity of Part I set a high standard.

In Part II, devoted to the radiological examination of the "normal" gastrointestinal tract, the first section includes a discussion of the anatomy of the "normal" stomach and the inherent mobility and adaptability of the abdominal viscera. In this section the alimentary tract is considered as a whole and the justifiable conclusion is reached that an alimentary tract may approximate the average, but that there is no fixed standard of normality. The factors influencing the form and position of the stomach, the effects of posture and respiration and the mobility and adaptability of the viscera are discussed in detail.

Section II of Part I, devoted to physiology, reviews the movement of food from mouth to anus as observed by the radiologist. The process of swallowing, gastric peristalsis, pyloric sphincter activity as well as the intestinal movements, are all portrayed radiographically. The author's discussions are thought-provoking as can be seen from his statement that gravity and tonic action appear to play a part in the control of the pyloric sphincter but that the peristaltic waves seem to be identical whether the sphincter relaxes or not. Moreover, he is certain that the opening of the pylorus does not depend on the acidity or alkalinity of the food.

On the basis of this thorough presentation of anatomy and physiology the author develops Part III which is devoted to pathology. From the esophagus and through the colon, in logical sequence, the reader has presented to him a fascinating discussion of "roentgenologic pathology." An excellent chapter on the gall-bladder is included.

The author never attempts to be dogmatic and often admits the inadequacies of roentgenologic diagnosis, as, for example, in his discussion of gastritis

The last quarter of the book presents seven appendices which must be invaluable to the roentgenologist and especially to the beginner in this specialty. The bibliography is apparently up to date and the division of indices into both an author and a general index, is always a convenience to the reader.

The book represents a well written, well illustrated text which could only be the outcome of an unusual roentgenologic experience.

S. M.

Dr Roy R Kracke (Fellow) Emory University, Ga, has been elected a member of the American Board of Pathology for a term of six years Dr Kracke is also chairman of the Section on Pathology and Physiology of the American Medical Association

Dr William E Robertson (Fellow), Philadelphia, is now President of the Philadelphia County Medical Society Dr Louis H Clerf (Fellow), Dr Michael A Burns (Fellow) and Dr Isadore Kaufman (Fellow) are directors

Dr E J G Beardsley (Fellow), Philadelphia, is Secretary-Treasurer of the American Association of the History of Medicine

Dr William D Stroud (Fellow), Philadelphia, is President of the Philadelphia Heart Association, Dr David Riesman (Fellow), Vice President Dr Thomas M McMillan (Fellow), Secretary, Dr Edward E Krumbhaar (Fellow), a member of its board of governors

Dr Ross McClure Chapman (Fellow), Towson, Md, is President of the American Psychiatric Association, Dr J Allen Jackson (Fellow), Danville, Pa, and Dr Walter L Treadway (Fellow), U S Public Health Service, are members of the executive committee

Dr Edward S Sledge (Fellow), Mobile, Ala, is President of the Alabama State Medical Association

Dr Paul A Yoder (Fellow), Winston-Salem, N C, is President of the Eighth District Medical Society of that State

Dr John W Tappan (Fellow), El Paso, Tex, has been made Health Officer of the El Paso City and County Health Unit

Dr Dudley C Smith (Fellow) is President of the University of Virginia Medical Society

Dr Charles W Waddell (Fellow), Fairmont, W Va, is President of West Virginia State Medical Association, Dr A A Shawkey (Fellow) Charleston, is Second Vice President and Dr T M Barber (Associate), Charleston, is Treasurer

The Fifth International Congress of Radiology was held in Chicago, September 13 to 17, with a large delegation from Europe, Mexico, Canada and South America. This was the first time the Congress has met in the United States. Dr B H Orndoff (Fellow), Chicago, was Secretary of the Congress, Dr Arthur C Christie (Fellow), Washington, was chairman of the Executive Committee, Dr George E Pfahler (Fellow), Philadelphia, was an honorary vice president

Dr E H Shuller (Associate), McAlester, Okla, is President of the Southeastern Oklahoma Medical Association

Dr J A Myers (Fellow), Chief of the Chest Clinic at the University of Minnesota and President of the National Tuberculosis Association, will be the guest speaker at the Post-Graduate Course on Tuberculosis to be conducted in Oklahoma City, October 13

Dr Clarence H Webb (Fellow), Shreveport, La, is President of the Louisiana State Pediatric Society

Dr Horace W Soper (Fellow), Dr Frank D Gorham (Fellow) and Dr Lee Pettit Gay (Fellow), all of St Louis, are President, Vice President and Treasurer, respectively, of the Missouri Society for the Advancement of Gastro-enterology

Dr Henry K Speed (Fellow), Sayre, Okla., is President-Elect of the Oklahoma State Medical Association

Dr O B Kiel (Fellow), Wichita Falls, Tex., is President of the Texas State Board of Medical Examiners

Dr Edward H Schwab (Fellow), Galveston, Dr M D Levy (Fellow), Houston, and Dr Robert M Barton (Fellow), Dallas, are President, Vice President and Secretary-Treasurer, respectively, of the Texas State Heart Association

Dr Bedford Shelmire (Fellow), Dallas, is President of the Texas Dermatological Association

Dr John G Young (Fellow), Dallas, is President of the Texas Pediatric Society

Dr John A McIntosh (Fellow), San Antonio, is Second Vice President of the Texas Neurological Association

Dr May Owen (Fellow), Fort Worth, Tex., recently received the honorary degree of Doctor of Science, conferred by the Texas Christian University

Dr Edward J Van Liere (Fellow), Morgantown, has been appointed Dean of the West Virginia University School of Medicine

Dr Ernest D Hitchcock (Fellow), Great Falls, is Vice President of the Montana State Medical Association

Dr David Riesman (Fellow), Philadelphia, emeritus professor of clinical medicine and professor of the history of medicine, University of Pennsylvania School of Medicine, was recently the recipient of the honorary degree of Doctor of Laws, conferred by the University of Wisconsin

Dr Jacob C Geiger (Fellow), Director of Public Health for the City and County of San Francisco, was recently elected President of the Pasteur Society of Central California

Dr Russell H Oppenheimer (Fellow), Dean of Emory University School of Medicine and heretofore Superintendent of Emory University Hospital, Atlanta, has been made Medical Director of the Hospital

Dr Hugo A Freund (Fellow) was recently appointed a member of the Public Welfare Commission of Detroit

Dr James J McGuire (Fellow), Trenton, is Secretary of the New Jersey State Board of Medical Examiners

Dr William de B MacNider (Fellow), Chapel Hill, Kenan Research Professor of Pharmacology at the University of North Carolina School of Medicine has recently been appointed Dean, to succeed Dr Charles S Mangum

Dr Robert Finley Gayle, Jr (Fellow), Richmond, is one of the physicians ap-

pointed to a new board created to have supervision over state mental hospitals in Virginia

Dr Charles E Sears (Fellow), Portland, Ore, was elected President of the Pacific Northwest Medical Association during July

Dr T Grier Miller (Fellow), Philadelphia, Professor of Clinical Medicine in the University of Pennsylvania School of Medicine and Chief of the Gastro-Intestinal Section, Hospital of the University of Pennsylvania, will have charge of the newly established "Kinsey-Thomas Foundation for the Study and Treatment of Diseases of the Digestive System" at the University of Pennsylvania. The late Miss Frances T Kinsey provided \$200,000 in her will for the establishment of the Foundation

The estate of the late Dr James M Anders (Master), Philadelphia, amounting to over \$500,000, has been ordered distributed. Dr Anders' will provided bequests of \$2,000 to the Philadelphia County Medical Society Library Fund and \$1,000 to the Society's Aid Association. It also provided \$2,500 for the Board of Directors of the Philadelphia County Medical Society to be held in trust and to be used to meet the expenses of the Philadelphia celebration of the Annual Health Day, a project in which Dr Anders was deeply interested and which he founded. The residuary estate was left in trust, the income to go to Mrs Anders for life. When the trust is ended, \$50,000 is to go to the trustees of the University of Pennsylvania for the Endowment Fund of the Graduate School of Medicine of the University

Dr Thomas B Magath (Fellow), Rochester, Minn, has been chosen President-elect of the American Society of Clinical Pathologists

Under the presidency of Dr J Morrison Hutcheson (Fellow and Governor), Richmond, the Medical Society of Virginia will hold its annual meeting in Roanoke, October 12 to 14. Among the invited guests are Dr Russell L Cecil (Fellow), New York City, and Surgeon General Thomas Parran (Fellow and Governor), of the U S Public Health Service

Dr George B Lawson (Fellow), Roanoke, was recently reappointed by the Governor as a member of the State Board of Health, his term of office to continue until 1942

Dr Louise Taylor Jones (Fellow), McLean, Va, one of the Vice Presidents of the Medical Women's International Association, attended the Fourth Congress held in Edinburgh, Scotland, July 13 to 18

Dr Elizabeth Bass (Fellow), New Orleans, La, attended the Medical Women's International Association in Edinburgh, Scotland, July 13 to 18, as a councillor from the American Medical Women's Association

The degree of Doctor of Laws was conferred upon Dr C C Bass (Fellow), Dean of Tulane University School of Medicine by Duke University at the annual commencement, June 7

The Southern Tuberculosis Conference will hold its annual meeting at the John Marshall Hotel, Richmond, Virginia, September 29, 30 and October 1, 1937. Among the speakers will be Paul H Ringer, M D (Fellow), Asheville, North Carolina, J A Myers, M D (Fellow), University of Minnesota, Louis Hamman, M D (Fellow), Johns Hopkins School of Medicine, Horton Casparis, M D (Fellow), Vanderbilt University School of Medicine, L J Moorman, M D (Fellow), Oklahoma City

OBITUARIES

DR JOSEPH LEGGETT MILLER

Dr Joseph Leggett Miller (Fellow), Chicago, Ill., died near Great Falls, Montana, on August 6. Death was sudden. He had gone to Montana on his annual vacation. Dr Miller was a native of Kewanee, Illinois, where he was born November 24, 1867. He received his Bachelor's degree from the University of Michigan in 1893. Two years later he graduated in Medicine at Northwestern University Medical School. He served his internship at Mercy Hospital in Chicago, and then became associated with Dr Frank Billings.

Dr Miller became a teacher at Rush Medical College in the Department of Medicine, eventually becoming Professor of Medicine. Since 1924 he was Clinical Professor of Medicine at the University of Chicago. For years he was a member of the Attending Staff at the Cook County Hospital. For some time he served as president of the Staff. For many years he was Attending Physician at St. Luke's Hospital.

He was a member of the American Medical Association, having served as secretary of the section on Practice of Medicine for five years, and as chairman of the same section in 1908-1909. He was a member of the Association of American Physicians, the American Society for Clinical Investigation and the Central Society for Clinical Research. He was a member of the Chicago Society of Internal Medicine, which he once served as president. Likewise he was a member and past president of the Chicago Institute of Medicine. He was also a member of the Chicago Medical Society and the Illinois Medical Society. He had been a member of the American College of Physicians since 1929.

He served in the World War, first as Major and later as Lieutenant Colonel in the Medical Corps. For many months he was chief of the Medical Department at Camp Dodge. From 1909 until 1931 he was Editor-in-Chief of the Archives of Internal Medicine. He also contributed largely to medical literature. Dr Miller had a wide reputation as a teacher and investigator and a contributor to the literature. He had a great gift for friendship, he was widely known, admired and beloved, unassuming and frank in conversation, exceptionally clear and direct in his teaching, a genial companion and loyal friend, and a physician who exemplified the old virtues of which the profession is so proud.

JAMES G. CARR, M.D., F.A.C.P.,
Governor for Northern Illinois

DR JUDSON DALAND

The death of Dr Judson Daland (Fellow) of Philadelphia on August 14, 1937, at 77 years of age removes a well known distinguished and

picturesque personality from the medical profession and from the citizenry of his adopted city and state

Dr Daland had been in ill health for two years, as the result of an automobile accident in England and from a subsequent major operation, and his passing was a happy release from increasing infirmities. Born in New York, in 1860, Judson Daland attended the medical school of the University of Pennsylvania and graduated in 1882. Shortly after his graduation he established his practice in Philadelphia and began forming the professional associations of a long and active life.

He was, from his earliest years, deeply interested in all aspects of science, especially biological science, and soon became interested in teaching and, early, affiliated with the Medico-Chirurgical Medical School and Hospital. Revealing his ability, talent and worth as a medical practitioner, investigator, teacher and writer Dr Daland was advanced in teaching positions until he became, in 1903, the Professor of Clinical Medicine in the Medical School and Attending Physician to its Hospital. Judson Daland's greatest contribution to clinical medicine was in emphasizing and reemphasizing the direct relationship of focal infections in the teeth, tonsils and sinuses to local (and frequently misunderstood) symptoms and to the general health conditions of patients at a period in medical history when such a relationship was denied, ignored and, all too often, derided by the majority of the, so termed, leaders of the medical profession. Dr Daland was, from his earliest years in medicine, deeply interested in tropical diseases and pursued knowledge in this subject in many lands. He was one of the earliest observers to point out that tropical diseases were to be found remote from the tropics and he had many opportunities of illustrating the truth of his statement by demonstrating patients in his Philadelphia clinic that were suffering from such maladies as pellagra, sprue, yaws, filariasis, beri-beri, quartan malaria and leprosy. In no Philadelphia clinic of that period was as much attention given to the seldom encountered disorders as was true in Dr Daland's service and the reason for this is to be found in Dr Daland's frequent visits to the tropical countries and his entire familiarity with the diseases of those sections.

During Dr Daland's active professional life he was a much sought consultant and served in such a capacity in a number of the city's and state's hospitals.

When the Medico-Chirurgical Medical School merged with the Medical School of the University of Pennsylvania to become the Graduate School of that great institution Dr Daland became a Professor of Clinical Medicine in the Graduate School and continued this association until his retirement from practice when he became Emeritus Professor of Clinical Medicine.

Dr Daland was an exceptional man in the medical profession for, in addition to being a nationally and internationally recognized expert in medical science, he was, perhaps, even better known as a world traveller.

an archeologist, a paleontologist, a connoisseur of art, a musician of ability, an accomplished linguist and a sportsman well known in many of the obscure corners of the world. In recent years Dr Daland has devoted much time and thought to the activities of the Philadelphia Institute for Medical Science, now active within the walls of the Philadelphia General Hospital, of which organization he was one of the founders and its first president and to which, it is said, he has bequeathed his \$200,000 estate.

Dr Daland represented an unusual type of a rapidly passing generation. Is it not possible that his life, his experiences, his education, that continued to the very end of his life, hold a lesson for the members of a younger generation?

Here was a physician who possessed an exceptional education in medicine and in life. He was cultured, travelled and truly learned but the more he knew the more modest he became concerning his many accomplishments and the more conscious he was of his ignorance concerning many of life's secrets. It is said that he wished his ashes to be placed in an urn in the Philadelphia Philosophical Society's rooms where he had spent so many pleasant hours and that upon the urn he wished placed the words, "I sought Truth."

Could any physician desire a better epitaph?

E J G BEARDSLEY, M D , F A C P ,
Governor for Eastern Pennsylvania

DR ELMER L EGGLESTON

Dr Elmer L Eggleston (Fellow), Battle Creek, Mich., died after three days' illness, July 7, 1937, of coronary thrombosis.

He was born in Marion, Iowa, in 1874. He received his M D degree from American Medical Missionary College (Chicago), 1900. He did post-graduate work at the New York Post-Graduate Medical School in Vienna. At the time of his death, he was head of the Department of Internal Medicine, Group B, Battle Creek Sanitarium. He was the author of several published articles, usually pertaining to gastroenterology. Dr Eggleston was a member of the Northern Tri-State Medical Society, Mississippi Valley Medical Society, Calhoun County Medical Society, Michigan State Medical Association, and a Fellow of the American Medical Association. He was elected a Fellow of the American College of Physicians on April 6, 1922.

His medical career was entirely devoted to institutional work at the Battle Creek Sanitarium, having taken his internship there and followed as assistant physician and finally head of the above mentioned department. For approximately 20 years he devoted himself largely to the subject of gastroenterology. Dr Eggleston possessed an unusual personality and with it went a keen mind and a sympathetic character, which fitted him so admirably for his medical career. During his years of work he met a great many prominent people from all parts of the United States, all of whom

became his devoted friends. They all appreciated his sympathetic personal devotion to them. He had an aptness for recognizing not only their physical ills, but also was able to help them adjust themselves to any complexes they might have established as a result of anxiety, worry and trouble. Each year he witnessed the return of old patients and many patients referred by Doctors and friends, which proved above everything else his success as a physician. He had many local friends and patients who leaned heavily on him and his death was a shock to not only these, his friends and neighbors, but to former patients in all parts of the county. Scores of telegrams and floral tributes further proved the love and esteem of those that knew him.

A paragraph from an editorial portrays Dr. Eggleston as he was known at home: "The professional loss through Dr. Eggleston's passing will be widely recognized. But Battle Creek, to which he belonged and into which he built the strong attachments of Home, grieves for the loss of a friend and fellow citizen who made himself endeared here because, in so many ways of helpful service, he had practiced that philosophy which he gave to the troubled patients—and had made the most of his todays."

M. A. MORTENSEN, M.D., F.A.C.P.

DR. JACOB FOWLER AVERY

Dr. Jacob F. Avery, a Fellow of the College, died at La Jolla, California, June 25, 1937. Dr. Avery had been retired from active practice for the past four years due to coronary disease, which resulted in his death.

Dr. Avery was born at Poughkeepsie, New York, January 19, 1873. He was graduated from Minneapolis Central High School in 1892 and from the University of Minnesota, College of Medicine, class of 1899. Following his internship at the City Hospital (now Minneapolis General Hospital), Dr. Avery practised in Virginia and Aitken, Minnesota before locating in Minneapolis in 1906. He retired from active practice in April 1932.

Dr. Avery was elected to membership in the Hennepin County Medical Society December 3, 1906. He became an Emeritus member in 1933 and an affiliate member of the Minnesota State Medical Association the same year.

He was married to Mary L. Esmond, June 4, 1902, who, with one son, Esmond Avery, of Detroit, Michigan, survives him.

Dr. Avery was commissioned a Captain in the Medical Corps, U. S. Army, July 10, 1917, and served with the 44th Infantry and the 39th Field Artillery at Camp Lewis, Washington. He was discharged at Camp Dodge, Iowa, October 14, 1919. For two years he served as chief of Medical Hospital Service in Minneapolis (this was forerunner of the Veterans' Administration).

He was a Fellow of the American College of Physicians and, until his

retirement, a member of the Minnesota Society of Internal Medicine In Minneapolis he was a member of the staffs of Northwestern Hospital and Abbott Hospital

JAMES F CHURCHILL, M D , F A C P ,
Governor for Southern California

DR FRANK ALSWORTH WAPLES

Dr Frank Alsworth Waples (Fellow), Houston, Texas, died March 3, 1937 He was born in New Orleans, Louisiana, in 1868 He held the degrees of Bachelor of Science and Doctor of Medicine from the University of Michigan From 1894-98, he was in charge of a general hospital in Kolgan, China From 1905-10, he conducted a private hospital in Cody, Wyo He was later on the staff of the Clifton Springs Sanatorium, of Clifton Springs, N Y, and Phelps Sanatorium, Battle Creek, Mich He later joined the staff of the Southern Pacific Hospital at Houston, Texas, and was internist to the Southern Pacific Lines

Dr Waples was a member of the Harris County Society, Texas State Medical Association, American Medical Association, and had been a Fellow of the American College of Physicians since 1920

DR AUGUSTUS WARREN CRANE

Dr Augustus Warren Crane (Fellow), Kalamazoo, Michigan, died February 20, 1937, of coronary thrombosis Dr Crane was born in Adrian, Mich, in 1868 He received his medical training at the University of Michigan Medical School, graduating in 1894 He was a member and past-president of the American Roentgen-Ray Society, a member of the Radiological Society of North America, a member of the American College of Radiology, an honorary member of the London Roentgen-Ray Society, a member and past-president of the Kalamazoo Academy of Medicine and Michigan Association of Radiologists In 1921 he was awarded the gold medal by the Radiological Society of North America He was a former acting editor and later a member of the editorial board of the *American Journal of Roentgenology* Kalamazoo College and the University of Michigan both honored him by conferring honorary degrees upon him He was chairman of the Kalamazoo County Section of the Michigan State Committee of Medical Preparedness, and was a member of Michigan Medical Advisory Board during the World War

DR JAMIE W DICKIE

Dr Jamie W Dickie of Southern Pines, N C, was born near Henderson, N C, October 25, 1893, the son of George T and Manolia Coppedge Dickie He graduated from Wake Forest College in 1914, receiving his

doctor's degree from Jefferson Medical College in 1917, and immediately joined the U S Navy Medical Corps, and was stationed at Fort Lyons, Colorado. He received his discharge in 1919, and for two years became associated with the late Dr W L Dunn of Asheville, specializing in pulmonary diseases.

He then went to Southern Pines, N C, where he established Pine Crest Manor Sanatorium, which has been in successful, continuous operation since. This institution is devoted to the study and treatment of pulmonary diseases.

Dr Dickie did postgraduate work on many occasions, having spent the entire past winter at the University of Pennsylvania and at Peter Bent Brigham Hospital in Boston. He had only returned to his work a few days when he was taken with pneumonia from which he died July 6, 1937.

His publications were not numerous, and were on subjects related to the chest. As an avocation, however, he wrote short stories and poems, and was widely interested in literature, particularly biography.

He was a member of his County and State Medical Societies, a Fellow of the American Medical Association, and became a Fellow of the American College of Physicians in 1936. He was a director of the North Carolina Tuberculosis Association and a member of the National Tuberculosis Association.

He was a member of the Episcopal Church. He leaves in addition to his wife, who was Miss Inez Benthall, a son, David Henry, and one daughter, Jane.

Dr Dickie was a man of great personal charm, of good judgment and wide knowledge in his chosen sphere of medical activities, and his sudden passing at an all too early age will leave a gap in the medical profession of this section that will be hard to fill.

C H COCKE M D , F A C P

Governor for N Carolina

A Real Achievement

IN HIGHER CONCENTRATION and REFINEMENT of SCARLET FEVER ANTITOXIN (NATIONAL)

(Refined and Concentrated Globulin)

Refinement and concentration of the pseudoglobulin fraction reduces volume 75 per cent and decreases serum reactions because of low content of foreign proteins

Lessens pain of injection

Smaller volume is more quickly absorbed

Gives quicker therapeutic response

Therapeutic Dose

Prophylactic Dose

SYRINGES SHOW EXACT SIZE

Each package of National Antitoxin or Curative Serum contains, as illustrated, an ampul vial of 1 to 10 dilution of serum for the cutaneous or scratch test to determine sensitivity of the patient

PROPHYLACTIC DOSE

2,000 Units U S Public Health Service
(100,000 original neutralizing units) are
contained in $\frac{1}{2}$ cc volume

THERAPEUTIC DOSE

6,000 Units U S Public Health Service
(300,000 original neutralizing units) are
contained in $1\frac{1}{2}$ cc volume

Each prophylactic or therapeutic dose contains 30 per cent excess units to insure potency beyond expiration date stamped on each package, and is furnished in sterile syringes with rustless (chromium) steel needles

The advantages of a highly refined and concentrated Scarlet Fever Antitoxin should materially increase its use for protection (passive immunity) of susceptible patients exposed to scarlet fever, and for the treatment of scarlet fever patients

When life itself seems threatened and Restful Sleep is *Essential*

MOST patients are not used to being ill and their fear of the consequences of illness or of operative procedure may result in insomnia and rob them of needed rest. If the condition persists, it may even seem to threaten life itself. The use of a safe sedative and hypnotic often proves valuable.

Ipral Calcium (calcium ethylisopropylbarbiturate) is a safe and effective sedative and hypnotic. It acts chiefly on the higher cerebral centers and produces a sleep closely resembling the normal, from which the patient awakens calm and generally refreshed. It is readily absorbed and rapidly eliminated. Undesirable cumulative effect may be avoided by proper

regulation of the dosage. No digestive disturbance or untoward organic effects have been reported.

Ipral Calcium is supplied in 2-gr tablets and in powder form for use as a sedative and hypnotic.

Ipral Sodium (sodium ethylisopropylbarbiturate) is supplied in 2-gr capsules for hypnotic use and in 4-gr tablets for preanesthetic medication.

Ipral Calcium (Powder) is available in 1-oz bottles. Tablets Ipral Calcium 2 gr, Tablets Ipral Sodium 4 gr and Capsules Ipral Sodium 2 gr are available in bottles of 100 and 1000.

Effect of Salyrgan Suppositories increase of urinary excretion and loss of weight (water) in a case of cardiorenal edema

RAPID CLEARANCE of EDEMA

Striking clinical improvement

THERE is no question as to the great value of Salyrgan in relieving dropsy in edema due to cardiac and cardiorenal disease. As the conditions for which this potent diuretic is indicated are of chronic character, there is a place for Salyrgan in a more conveniently applicable form: suppositories. Salyrgan Suppositories are serviceable as a supplement to parenteral administration of the drug as well as for sole medication when injections are not advisable or feasible.

DOSAGE One suppository at intervals of three days or more (inserted preferably in the morning, so that the diuresis will not interrupt the patient's nocturnal rest).

HOW SUPPLIED Salyrgan Suppositories (each containing 0.4 Gm) are available in boxes of 5 and 25, Salyrgan Solution (10%) in ampules of 1 cc, boxes of 5, 25 and 100, and 2 cc, boxes of 10, 25 and 100.

LAMOTTE Urine pH Comparator

*For Accurate Study of Urine Reaction
in Acidosis, Alkalosis or Special
Dietary Work*

THIS simple, compact outfit is being widely used in the routine examination of urine reaction, because of its great convenience and accuracy. The urine specimens are treated directly with the LaMotte Duplex Indicator—without dilution. The color resulting from the reaction of the urine is then compared with known color standards and promptly identified. Accurate to 0.2 pH. Time per test, 5 minutes. Also used for pH of feces. (levo meta-methylaminoethanolphenol hydrochloride)

EMULSION

**Reduces
Nasal
Engorgement
in Colds**

Neo-Synephrin Emulsion may be used in children as well as adults for relief of nasal congestion and discharge in colds, rhinitis and sinusitis

The instillation of a few drops into the nasal cavities will quickly

and effectively constrict the engorged mucosa without sting or other untoward effects

SOME OF THE ADVANTAGES OF NEO-SYNEPHRIN EMULSION ARE

- 1 No sting
- 2 More sustained action than epinephrine or ephedrine
- 3 Less toxic in therapeutic dosage than epinephrine or ephedrine
- 4 So stable that it may be sterilized by boiling
- 5 In the doses recommended Neo-Synephrin usually does not produce nervousness or insomnia

DOSAGE FORMS

NEO-SYNEPHRIN HYDROCHLORIDE EMULSION,

1/4%—(1-oz bottle with dropper)

NEO-SYNEPHRIN HYDROCHLORIDE SOLUTION,

1/4% for dropper or spray, 1% for resistant cases

ANNALS OF INTERNAL MEDICINE

OFFICIAL PERIODICAL OF THE AMERICAN COLLEGE OF PHYSICIANS

Place of Publication—Prince and Lemon Sts, Lancaster, Pa

Editorial Office—University Hospital,
Baltimore, Md

Executive Office—4200 Pine Street,
Philadelphia, Pa

THE ANNALS OF INTERNAL MEDICINE is published by the American College of Physicians. The contents consist of contributions in the field of internal medicine, editorials, book reviews, and a section devoted to the affairs of the College.

MANUSCRIPTS All correspondence relating to the publication of papers and all books and monographs for review should be addressed to the editor. No manuscripts will be accepted without his consideration. Bibliographic references are to conform to the following style.

4 Doe, J E. What I know about it, Jr. Am Med Assoc, 1931, *xcvi*, 2006-2008.

Six illustrations per article are allowed without cost to the author. Beyond this number the author must pay the actual cost of illustrations.

REPRINTS For each article published, there will be furnished gratis fifty reprints without covers. An order slip for additional reprints, with a table showing cost, will be sent with galley proof to each contributor. If additional reprints over the first fifty are wanted the order slip must be returned to the printer at the time corrected galley proofs are sent to the Editor.

REVIEWS The ANNALS will make an especial feature of the reviews of monographs and books bearing upon the field of internal medicine. Authors and publishers wishing to submit such material should send it to the editor. While obviously impossible to make extended reviews of all material, an acknowledgment of all books and monographs sent will be made in the department of reviews.

SUBSCRIPTION This periodical is issued monthly, new volumes beginning with the July number each year. Subscriptions may be by the volume or year, but the volume basis is especially recommended. Volumes will consist of approximately 1,400 pages. Subscription price per volume, or per annum, net postpaid: \$7.00, United States, Canada, Mexico, Cuba, Canal Zone, Hawaii, Porto Rico, \$7.50, other countries. Prices for back volumes or numbers furnished upon application. Single numbers, current volume, when available, \$1.00. Members of the American College of Physicians receive the ANNALS OF INTERNAL MEDICINE as a part of their membership. Checks should be drawn to the order of W. D. STROUD, M.D., Treasurer, and remitted through the Publication Office or the Executive Secretary's Office.

BUSINESS CORRESPONDENCE All correspondence relating to business matters, advertising, subscriptions to the ANNALS, inquiries concerning membership in the American College of Physicians, et cetera, should be addressed to the Publication Office or to the Executive Secretary. Books and reprints presented to the College Library should be addressed to the Executive Secretary.

THE THYROID AND ITS DISEASES

By J. H. Means, M.D., F.A.C.P.

Jackson Professor of Clinical Medicine, Harvard University,
and Chief of the Medical Services, Massachusetts
General Hospital

THIS is an authoritative book, written on the medical and pathologic aspects of thyroid. It is based on actual experiences—actual observations—actual treatments over a period of more than two decades. It is an indispensable aid to all practitioners who treat thyroid affections, medically or surgically, because the personal experiences recorded are those of a group of outstanding specialists—collaborating with Dr Means—in the Thyroid Clinic of the Massachusetts General Hospital.

The author discusses the gland, the hormone, the relation of the hormone, the relation of the hormone to its endocrine partners, the pathology and symptomatology of the thyroid, methods of examination, classification, simple goiters, myxedema and cretinism, toxic goiters (including iodine response and surgery), nodular, malignant and inflammatory goiters, anomalies of the thyroid, thyroid administration and total thyroidectomy in diseases of other than thyroid origin, and fact and fancy in matters thyroid. 602 pages 73 charts and illustrations \$6 00

(New, March 1937)

TREATMENT BY DIET

By Clifford J. Barborka, M.D., F.A.C.P.

Department of Medicine, Northwestern University Medical
School, Chicago, Formerly Consulting Physician,
The Mayo Clinic

HERE is no ordinary textbook on diet, but a book which presents a practical, workable, systematic method of prescribing diets and applying treatments which thousands of doctors have been using with excellent results. Dr Barborka is an eminent practicing physician who has written a live, vital presentation of this important subject. This new third edition, *just out*, includes a broadened treatment of obesity. The present status of the clinical aspects of protamine insulin is fully covered. There are splendid illustrations and charts of comparative servings of various types of food, giving both gram weight and household measure. Complete charts give distribution of food allowance for various caloric diets. The material is arranged by diseases first, those in which diet is of paramount importance, second, those in which it is of varying importance. This is an authoritative text written by a practitioner who is proving the efficacy of his treatments in his constantly widening practice. Illustrated \$5 00

ORTHODIASCOPY

An Analysis of Over Seventeen
Hundred Orthodiascopic Examinations

By Chester M. Kurtz, M.D., F.A.C.P.,
*Assistant Professor of Medicine, University of Wisconsin,
Cardiologist, State of Wisconsin General Hospital*

Orthodiascopy is as valuable in the treatment of cardiac conditions as in the diagnosis of them. This book describes the apparatus used and the details of the procedure. The use of the orthodiascope provides unusual efficiency not only in determining heart size and detecting early stages of cardiac enlargement but also in revealing certain easily distinguishable changes in the shape of the cardiovascular shadow characteristic of various types of heart disease. It enables the examiner to detect an early lesion of the mitral valve and, as a corollary, to differentiate between a functional and organic apical systolic murmur. Nomograms, which determine without calculations the predicted frontal area and transverse diameter, are included. Another important feature covered in this monograph is the correlation between the common physical signs and the orthodiascopic findings, lending new significance to ordinary procedures.

Probably \$3 50

ARTERIOVENOUS ANEURYSM

By

Emile Holman, A.B., B.A., Oxon., M.D., *Professor of Surgery, Stanford University Medical School, Surgeon-in-Chief, Lane and Stanford University Hospitals*

The author presents in this book the characteristics of this unusual lesion as manifested in the experimental animal and in clinical cases. Many of these characteristics, which are quite unique, and which have long puzzled students of the subject, are here for the first time adequately explained and described. The book covers subjects not ordinarily embodied in textbooks of medicine or surgery, such as acquired and congenital fistulae of the peripheral vessels, mycotic fistulae, congenital and experimental fistulae of the heart, and intracerebral fistulae of congenital and acquired origin. It presents the subject of arteriovenous communications as a physiological problem in the hydrodynamics of the circulation, and provides a simple explanation of the unique phenomena exhibited by such communications whether they are located in the heart or in the peripheral vessels. This book will prove invaluable as a reference for the internist.

Theocalcin

Council Accepted

In Congestive Heart Failure

For the reduction of edema and to diminish dyspnoea, give 1 to 3 tablets of Theocalcin, three times a day. Theocalcin, theobromine-calcium salicylate is a well-tolerated diuretic and myocardial stimulant for oral administration.

Available as 7½ grain tablets and in powder form

Bilhuber-Knoll Corp. 154 Ogden Avenue
JERSEY CITY, N. J.

ALKALINIZATION

by the physiological process

WHERE buffered alkalinization is desirable—as during sulfanilamide administration, in the treatment of colds, influenza and other seasonal respiratory affections—Kalak offers these clinical advantages

- (1) It presents a balanced combination of bicarbonates in solution
- (2) It contains the mineral substances normal to the blood (and no other)

Kalak's high buffering value helps to maintain the urinary pH of 7.4 which has been found so desirable in sulfanilamide therapy

KALAK

is synthetically prepared—is hypertonic, uniform in composition, definite in alkali potency

KALAK WATER COMPANY OF NEW YORK, INC., 6 CHURCH STREET NEW YORK CITY

The Important Industrial Heart

EMPLOYERS today are definitely concerned with the health of their employees for economic as well as humanitarian reasons. This is particularly true in occupations where sudden incapacity of an individual might cause a serious accident with subsequent injury to others. It is obvious, therefore, that the vascular condition of the heart is especially important, and accounts for the prominence placed upon the cardiac division of the medical department of large companies.

The increasing number of "Hindle" Electrocardiographs in use in Industrial Medicine is significant and of interest to the Cardiologist within and outside industry. In the first place, such large companies are guided in their selection by their own or consulting Cardiologists who have been trained upon the "Hindle." Secondly, industrialists have excellent facilities for appraising values of such equipment and insist upon getting their money's worth.

Every purchaser of a "Hindle" obtains an instrument whose records are acceptable to the entire medical world—a rugged instrument which assures a lifetime of accurate performance.

'All-Electric' Models are made in stationary, mobile and portable types for use in hospitals, clinics and private offices

Acute Rhinitis in Children

FIG 1 J M C White, female, age 4 June 5, 1936 Acute rhinitis 11 40 A M Two inhalations of 'Benedrine Inhaler'

FIG 2 11 50 A M Maximum shrinkage evident

In 100 cases of acute rhinitis in children from two months to twelve years of age treated with 'Benedrine Inhaler' Scarano and Coppolino report prompt and adequate shrinkage of the nasal mucosa in 97 per cent — Arch Pediat 54 97, 1937

The vapor form—in addition to its greater effectiveness—overcomes the strenuous objections which children show to liquid inhalants as applied by drops, tampons or sprays Obviously, however, as with any medication for children, an adult should supervise the use of the Inhaler and retain possession of the tube

BENZEDRINE INHALER

A VOLATILE
VASOCONSTRICTOR

Each tube is packed with benzyl methyl carbinamine, S K F, 0.325 gm oil of lavender, 0.097 gm, and menthol 0.032 gm 'Benedrine' is the trade mark for S K F's nasal inhaler and for their brand of the substance whose descriptive name is benzyl methyl carbinamine

SMITH, KLINE & FRENCH LABORATORIES • PHILADELPHIA, PA.
ESTABLISHED 1841

"IT HAS BEEN ESTIMATED¹ that in the United States annually one-half million people with late syphilis seek treatment for the first time " It is hoped that these figures will be reduced as a result of the many publicity campaigns now under way These patients will require careful supervision and persistent treatment

Two Squibb preparations—Neoarsphenamine and Iodobismutol with Saligenin—have been found to be very effective in the treatment of syphilis Neoarsphenamine Squibb is designed to produce maximum therapeutic benefit It is subjected to exacting controls to assure a high margin of safety, uniform strength, ready solubility and high spirocheticidal activity Equally

effective when indicated are Arsphenamine Squibb and Sulpharsphenamine Squibb

Iodobismutol with Saligenin is a propylene glycol solution containing 6 per cent sodium iodobismuthite, 12 per cent sodium iodide and 4 per cent saligenin (a local anesthetic) It presents bismuth largely in anionic (electro-negative) form Iodobismutol with Saligenin is rapidly and completely absorbed and slowly excreted, thus providing a relatively prolonged bismuth effect Repeated injections are well tolerated in both early and late syphilis

E·R·SQUIBB & SONS, NEW YORK
MANUFACTURING CHEMISTS TO THE MEDICAL PROFESSION SINCE 1858

● As a means of obtaining accurate dosage, and also as a convenience for your patients, the special minim dropper which is included in each 1-fluidounce package of Tincture Digitalis Squibb deserves consideration. This dropper delivers drops of exactly one minim each—no more, no less. This feature of the Tincture Digitalis Squibb 1-ounce package is another reason for prescribing it for your patients. The detachable label on the carton makes it possible for the pharmacist to conveniently dispense the Tincture and the dropper as one unit.

Tincture Digitalis Squibb has been known for over seventy-five years for its uniform potency. It is prepared from carefully selected digitalis leaves and in accordance with the method described in

the U S P XI. It is assayed and standardized by the U S P frog method. Each 1 cc is equivalent to 10 to 11 U S P XI (International) units. In addition to the 1-oz package described herein, it is distributed in 1, 4 and 16 fl oz and gallon bottles.

Also Available

AMINOPHYLLINE SQUIBB (Theophylline with Ethylene Diamine, U S P XI) is supplied in tablets of 100 mg ($1\frac{1}{2}$ gr) each, in vials of 10 tablets and bottles of 100 tablets. Aminophylline Powder is supplied in 10-Gm vials and 1-oz bottles for prescription use and for the preparation of solutions for rectal or parenteral administration. It is useful as a diuretic, as a myocardial stimulant and as an adjunct to digitalis therapy.

REGULATION

Regulation of the daily program, especially diet and exercise is beneficial, to normal bowel movement and in some cases of constipation serves as sufficient treatment. Others require additional aid to facilitate regular evacuation.

When an adjunct to diet and exercise is required, as it often is, Petrolagar provides a mild but effective

tive treatment. Its miscible properties make it easier to take and more effective than plain mineral oil. Further, by softening the feces Petrolagar induces large, well formed stools which are easy to evacuate. The five types of Petrolagar afford a choice of medication adaptable to the individual patient. Petrolagar Laboratories, Inc., Chicago

Petrolagar is a mechanical emulsion of pure liquid petrolatum (65% by volume) and agar agar. Accepted by the Council on Pharmacy and Chemistry of the American Medical Association for the treatment of constipation.

Petrolagar

Improved Antitoxins and Immune Serums

● Constant effort in the Lilly Research Laboratories further to concentrate and refine antitoxins and immune serums has resulted in a decrease in protein content per unit, a high unitage per cubic centimeter, a 35 to 50 percent reduction in dosage volume, and a lowered incidence of serum reactions

The following are supplied Anti-

meningococcic Serum,
Concentrated, Lilly, Diph-
theria Antitoxin, Puri-

fied, Concentrated, Lilly, Diphtheria

Knox Gelatine (U.S.P.) an Important Vehicle in GASTRIC DISTURBANCE DIETS

When advising a diet for gastric disturbances, remember that Knox Gelatine (U.S.P.) is a valuable vehicle. Knox Gelatine is not only an easily digested protein but blends with whatever foods are allowed into tempting salads and desserts.

In hyperacidity cases or in treating ulcers frequent meals are recommended. Jellyed fruit juice or a bland, slightly sweetened gelatine dessert is a variant to the usual between meal beverage.

Knox Gelatine is scientifically made from selected long, hard, shank beef-bones — surpasses minimum U.S.P. requirements — pH about 6.0 — contains no carbohydrates — fat content less than 0.1% — odorless — tasteless — bacteriologically safe.

*In daily menus and prescribed diets
use Knox Gelatine*

Recipe

Dessert with strained prune pulp,

PRUNE WHIP (six servings)

- 1 Soak Gelatine in cold water about 5 minutes, using
1 envelope Knox Sparkling Gelatine
 $\frac{1}{4}$ cup cold water
- 2 Add to the following, stirring thoroughly
 $\frac{3}{4}$ cup hot prune juice
1 cup cooked prune pulp
2 tablespoonfuls lemon juice
 $\frac{1}{2}$ cup sugar
 $\frac{1}{4}$ teaspoonful salt
- 3 Cool. When mixture begins to thicken, fold in
2 egg whites, stiffly beaten
- 4 Rinse mold or dish in cold water, and fill with dessert. Chill. To serve, unmold and garnish with whipped cream, or serve with custard sauce.

KNOX SPARKLING GELATINE

Critical investigators have found Mercurin Suppositories to be as efficient as the parenterally administered mercurial diuretics. Experienced cardiologists recommend Mercurin Suppositories in the treatment of Edema of Congestive Heart Failure, Nephrosis, and Cirrhosis of the Liver with Ascites, because the rectal administration of Mercurin is simpler and safer than the injection of mercurial diuretics.

SUPPLIED in boxes of 5 and 25 suppositories (0.5 Gm.)

MERCURIN SUPPOSITORIES

β methoxy γ hydroxymercuri propylamide of camphoric acid sodium salt (with 20% of the free acid)

*A trial supply and complete literature
are available on request*

CAMPBELL PRODUCTS, Inc. 79 Madison Ave. NEW YORK, N. Y.

At the first suspicion of pneumonia— TYPE IT!

PNEUMONIAS OF DIFFERENT ETIOLOGY are distinct diseases. Early specific treatment—so vital to successful serum therapy—is possible only when the type of pneumococcus is determined immediately.

The Neufeld method, for pneumococcus typing directly from sputum, is simple, accurate and permits of a diagnosis being made within a few minutes' time.

Although the technique of typing can be readily learned by any practitioner, the trend of usage is to convey sputum for the Neufeld tests to experienced pathologists or typing stations. Lederle has recently compiled a 'Directory of Typing Stations,' finding more than 1700 of them in the United States now and more being added constantly. They are well distributed and there is at least one within the easy reach of practically every physician. The swift development of this service in the last year, frequently fostered and advertised by state health boards, is eloquent testimony to the great growth of serum therapy.

"Antipneumococcic Rabbit Typing Sera Lederle" for Types I to XXXII, ready for immediate use, are available in the following packages:

FOR VITAMINS IN A PALATABLE FORM

MALTINE WITH COD LIVER OIL contains all the valuable factors of both Maltine and cod liver oil. These include the vitamins A and D of cod liver oil as well as all the ingredients of Maltine. Furthermore, constant laboratory tests on animals indicate that the vitamin A value of cod liver oil is enhanced *twofold* when emulsified with Maltine as in MALTINE WITH COD LIVER OIL. The only element obviously lacking in this 62 year old preparation is the distasteful oily consistency associated with vitamin-bearing oils.

MALTINE WITH COD LIVER OIL and IRON IODIDE is also available, containing two grains of freshly prepared iron iodide per fluid ounce. The Maltine Company, 60 Hudson Street, New York City.

Growth and Development of the Child, Part III, White House Conference on Child Health and Protection, New York, 1932, p 213

BUT—

many diets are acid-forming

ORDINARY cereals and cereal products, meat, and eggs—all produce an acid ash when burned in the body, yet they form the mainstay of the average diet. Although this preponderance of acid-forming foods is not definitely known to have great significance for the health of normal adults, a number of authorities advocate a basic or alkali-forming diet for children and pregnant women.

Infancy and Childhood. "Alkaline diets are essential for infancy where growth is rapid," declares Shohl. He calculates the need as 10 cc excess of 0.1 normal base per kilo per day.¹ Babies fed on breast milk stored an excess of base over acid, the range being from 31 to 56 cc 0.1 N base per day, is the finding of the Committee on Growth and Development of the White House Conference on Child Health.² Lippard and Marples observed greater increases in weight of infants receiving basic diets as compared with controls on acid-forming feedings.³

Pregnancy and Lactation. Shohl states, "Pregnancy and lactation require additional alkali—a minimum of 150 cc 0.1 N base per day."¹ Coons and associates, from acid-base balances taken upon normal pregnant women receiving basic diets, determined that the storage of basic substances was even greater than estimated by Shohl. "This may be some indication," they say, "of the magnitude of the maternal needs exclusive of fetus."⁴

As the chief alkali-forming foods are fruits, vegetables, and milk, the ordinary basic diet consisting of these foods is likely to be low in calories and often does not appease hunger. But Pablum—the only base-forming cereal*—offers a way to add muffins, cereal, puddings and similar "filling" foods to the usual basic diet. Pablum, moreover, is richer than ordinary cereals in calcium, phosphorus, iron, and copper and supplies vitamins B and G.

Pablum (Mead's Cereal thoroughly cooked) is a palatable basic cereal consisting of wheat meal, oatmeal, corn meal, wheat em bryo, alfalfa leaf, beef bone, brewers yeast, iron salt, and sodium chloride.

PABLUM
the only
alkali-
forming
cereal*

| Cereal | Base | Acid |
|--------------|------|------|
| PABLUM | 18 | |
| Farina | | 11.0 |
| Oatmeal | | 12.9 |
| Wheat, whole | | 11.5 |
| Cornmeal | | 5.3 |
| Barley | | 10.1 |
| Rice | | 8.1 |

Figures given in the above table are based on 100 grams of food and represent cubic centimeters of normal acid or base.

¹⁻⁴ Bibliography on request

*Mead's Cereal (Pablum in uncooked form) is also base forming

NUMBER 4

THE CLINICAL USE OF SULPHANILAMIDE AND ITS DERIVATIVES IN THE TREATMENT OF INFECTIOUS DISEASES*

By PERRIN H. LONG, M.D., and ELEANOR A. BLISS, Sc.D.,
Baltimore, Maryland

INTRODUCTION

THE experimental observations^{1, 2, 3, 4, 5, 6, 7} which have led to the use of sulphanilamide or its derivatives (chart 1) in the treatment of certain infectious diseases show that these chemicals have powerful chemotherapeutic effects in experimental infections. Clinical observations of their effects in human beings tend to confirm the laboratory results. In this communication we propose to discuss primarily the clinical application of these chemotherapeutic agents, and to detail the methods of their administration and the possible toxic effects which may become manifest in patients treated with sulphanilamide or its derivatives.

It is interesting to note that the first mention of these products in the medical literature was that of Foerster⁸ who reported that "Streptozon" (Prontosil) had shown a marked chemotherapeutic effect in a boy suffering from a generalized staphylococcal infection. This report was delivered to the Dusseldorf Dermatological Society on May 17, 1933. In the following year Grutz^{9, 10} reported that he had obtained good results in the treatment of toxic and septic erythemas by using "Prontosil" by mouth, and "Prontosil Solution" by the intravenous route. In the same year Veil¹¹ reported upon the use of "Prontosil Solution" in the treatment of "rheumatism."

Early in 1935 Gmelin¹² discussed the use of "Prontosil" and "Prontosil Solution" in the treatment of erysipelas in children and concluded that the results obtained were so satisfactory that extensive clinical trials were warranted. It is worthwhile to remember at this point that up until February 1935 no experimental data concerning "Prontosil" or "Prontosil

* Read at the St. Louis meeting of the American College of Physicians, April 20, 1937.
From the Department of Medicine, The Johns Hopkins Hospital, Baltimore, Maryland.
Our investigations have been made possible by a grant from the Chemical Foundation, Inc., of New York City.

Solution" had been reported. However, in that month, the first experimental report¹ was issued. It was accompanied by four more clinical papers dealing with the use of the dyes in various types of infectious processes^{13, 14, 15, 16}. These clinical reports dealt with the use of "Prontosil" and "Prontosil Solution" in the treatment of streptococcal thrombophlebitis, adenitis, otitis media, erysipelas, puerperal fever and infectious arthritis. In general, the therapeutic results obtained were good. However, there was a divergence of opinion as to the efficacy of these chemicals in staphylococcal infections, Anselm¹⁵ reporting favorable results, while Schreus¹⁴ was doubtful of their value.

Following these reports there were numerous communications in the German literature dealing with the use of "Prontosil" and "Prontosil Solution" in a variety of diseases. Imhauser¹⁷ reported that he had obtained good results when these agents were used in the treatment of infections due to *E. coli*. Recknagel¹⁸ believed that the chemicals were of value in pneumococcal and staphylococcal as well as streptococcal infections. Bingold¹⁹ reported a patient with Hodgkin's disease, who either was cured or developed a prolonged remission after treatment with "Prontosil". Einhauser²⁰ considered the drugs of great value in the treatment of sepsis, and Fuge²¹ found that all cases of pure streptococcal puerperal sepsis recovered after treatment with the "Prontosils". In his opinion staphylococcal infections were not benefited.

Roth²² found the drugs of value in hemolytic streptococcal infections, and Schranz²³ reported 60 patients ill with sepsis, treated with the "Prontosils," of whom 57 recovered. He advised that the chemicals be used as prophylactic agents before operative procedures in septic patients. Riecke²⁴ observed nine cases of purulent meningitis, all treated with these new compounds. Six of these cases had bacteria in cultures of their spinal fluid. Three of the nine patients recovered, but unfortunately, the author gave no data as to the spinal fluid findings in these patients. Scherber²⁵ used "Prontosil" in pemphigus vulgaris, and Kramer²⁶ reported good results from its use in 23 patients ill with erysipelas.

The first clinical report from France appeared in 1935. In that country, a product analogous to "Prontosil" called "Rubiazol" was being used. Vermelin and Hartemann²⁷ reported that they had treated patients with puerperal sepsis with "Rubiazol" by mouth and by the intravenous route since May 1935. Four of their patients developed severe reactions following the intravenous use of "Rubiazol" and one patient succumbed to the reaction. These observers considered the product with which they had been working as too toxic for further use. Following this report, Floch²⁸ described the good results that he had obtained in treating patients ill with tropical streptococcal lymphangitis with "Rubiazol". These patients were all treated with "Rubiazol" tablets by mouth. Lemierre, La Porte, Laudat and Daum²⁹ carefully studied the effects of "Rubiazol" upon the kidney which had been damaged by an acute hemorrhagic nephritis. They con-

cluded the drug did not augment existing renal impairment Meyer-Heine and Huguenin³⁰ studied the effects of the "Chlorohydrate of sulphamide-chrysoidine" in 150 patients ill with erysipelas Eight of these patients were infants all of whom recovered These observers noted no toxic effects and concluded that the chemical was a chemotherapeutic agent of great value Recently Bloch-Michel, Conte and Durel³¹ have reported that para-amino-benzene-sulphonamide and benzyl-para-amino-benzene-sulphonamide have shown very favorable therapeutic effects in the treatment of erysipelas While para-amino-benzene-sulphonamide was effective, these authors preferred to use the benzyl derivative Their results were striking as far as influencing the clinical course of the disease was concerned, and they reported no toxic effects from the use of the benzyl compound

The first experimental and clinical report concerning the use of the "Prontosils" in England was that of Colebrook and Kenny³ who, after preliminary tests in mice, applied these products to the treatment of puerperal fever In a carefully studied series of patients they noted, not only a remarkable therapeutic effect in many cases, but an actual lowering of the expected case fatality rate They stated that they had observed sulphemoglobinemia and mild renal irritation following the use of these drugs Later, in a more extended clinical report³² these observers concluded that the use of the "Prontosils" not only materially changed the clinical course of streptococcal puerperal infection, but also brought about a definite decrease in the expected case fatality rate These two papers by Colebrook and Kenny have served to bring the possibilities of these new chemotherapeutic agents to the attention of the English speaking physicians

Fouls and Barr³³ have recently described the beneficial effects of sulphanilamide in the treatment of puerperal sepsis These observers used large doses of the chemical, and but one of their 28 patients, of whom 11 had a septicemia, succumbed to her infection Their conclusions were that sulphanilamide had a marked chemotherapeutic effect and a low toxicity Peters and Havard³⁴ used sulphanilamide in the treatment of 150 patients ill with scarlet fever In the treated group, 35 per cent of the patients developed complications, while in an equally large parallel control group, 56 per cent of the patients developed complications This difference in the complication rate was considered statistically significant These observers noted but few toxic manifestations from the drug

In a preliminary report Schwentker, Gelman and Long³⁵ noted that sulphanilamide had a definite therapeutic effect in the treatment of meningococcal meningitis, and concluded that results obtained with chemotherapy seemed quite as good as those obtained by the specific antiserum Dees and Colston³⁶ have used sulphanilamide in the treatment of acute gonococcal urethritis and are "deeply impressed" with "the surprisingly prompt response to treatment" which they observed in the majority of their patients Hemtzelman and his associates³⁷ have recently reported favorable results

from sulphanilamide therapy in the treatment of a small series of Type III lobar pneumonia patients

We^{5, 38, 39, 40} have observed striking effects from the use of sulphanilamide and its dye derivatives in the treatment of experimental and clinical hemolytic streptococcal infections. Furthermore, we⁴⁰ pointed out, as did Rosenthal⁴² and Cooper, Gross and Mellon⁴³ that sulphanilamide had some therapeutic effect in the treatment of pneumococcal infections in mice. Recently we⁴¹ have observed that this chemical is effective in treating experimental *Cl. Welchii* infections in mice.

Thus, it seems that sulphanilamide, instead of being a chemotherapeutic agent specific for hemolytic streptococcal infections, is a drug possessing a broad chemotherapeutic valency. At the present time, enough experimental and clinical evidence exists to warrant the use of sulphanilamide or "Pron-tosil Solution" in the treatment of hemolytic streptococcal infections, and for the use of sulphanilamide in meningococcal infections. Its use in pneumococcal infection rests mainly upon experimental data which are not, as yet, conclusive. Clinical evidence alone supports the use of this chemical in gonococcal infections.

In evaluating the clinical effect of these new chemotherapeutic agents, in this report we will base our evidence solely upon the results obtained in the treatment of hemolytic streptococcal meningitis. It has been well recognized in the past⁴⁴ that this disease constituted an almost invariably fatal infection, with a case fatality rate of about 99 per cent. Hence, the reports of the case histories of patients recovering from this disease as the result of sulphanilamide therapy are of utmost importance in establishing the clinical value of sulphanilamide or its derivatives.

In 1936 Causse, Loiseau and Gisselbrecht⁴⁵ reported the first patient ill with hemolytic streptococcal meningitis who, after treatment with "Pron-tosil," made a complete recovery. This was followed by the report of Arnold⁴⁶ who treated a patient suffering from hemolytic streptococcal meningitis with sulphanilamide. Recovery took place promptly. Since this first report Arnold⁴⁷ has successfully treated five additional patients ill with hemolytic streptococcal meningitis. Shortly after Arnold's report, Schwentker and his associates⁴⁸ reported recoveries in three out of four patients ill with hemolytic streptococcal meningitis and treated with sulphanilamide. Subsequent to these reports, Anderson⁴⁹ has reported one case of streptococcal meningitis, and Weinberg and his associates⁵⁰ two cases of the same disease who have recovered after being treated with sulphanilamide or its derivatives.

In this report we will discuss the course and therapy in four additional patients ill with hemolytic streptococcal meningitis.

CASE REPORTS

Case 1 P. F., a seven year old white girl, was brought to the Harriet Lane Home of the Johns Hopkins Hospital in a comatose state on February 15, 1937.

Five weeks before entry into the hospital, she had had measles and a left ear ache. Four days before coming to the hospital, the child developed malaise, headache, fever and a left ear ache. Paracentesis of the left ear drum was performed and the ear discharged pus. On the day before entering the hospital, a headache and stiff neck appeared. Upon the morning of admission to Harriet Lane, the child was delirious and vomited. She became comatose while being brought to the hospital. The physical examination showed a comatose, moribund child. The pupils did not react to light, and there was a definite blurring of the nasal margin of the nerve head in the left eye. No mastoid swelling or stiffness of the neck could be elicited. Kernig's sign was negative. The remainder of the physical examination was essentially negative. Laboratory examinations: Urine, negative. Hemoglobin, 104 per cent. Sahl's, red blood cell count 5.4 millions, white blood cell count 38,200. Differential count, polymorphonuclears 45 per cent, juvenile polymorphonuclears 6 per cent, immature forms, 43 per cent, lymphocytes, 4 per cent. Cerebrospinal fluid, no increase in pressure, Pandy test 4 plus, white blood cells, 4,620, differential count, mononuclears 76 per cent, polymorphonuclears 24 per cent. Chains of gram positive cocci were seen in stained films of the cerebrospinal fluid. The Wassermann test was negative. Blood culture was negative. The culture of the cerebrospinal fluid showed a pure culture of Beta hemolytic streptococci. Cultures of the pus from the left external auditory canal showed Beta hemolytic streptococci, *Staphylococcus aureus* and *B. proteus*. Shortly after entry, 18 grams of sulphanilamide were administered by the parenteral route, and a transfusion of 80 c.c. of citrated blood was given. The patient died a few hours after entering the hospital.

Autopsy "The longitudinal sinus is open. The brain is normal except that the meninges over the median portion of the base of the cerebellum, over the medulla and pons and extending up to the Sylvian fissure and optic chiasm show a whitish opacity. On section the ventricles are normal. The brain substance looks normal." Bacteriological cultures of the meninges showed Beta hemolytic streptococci.

Case 2 W. H., a nine year old white boy, was admitted to the Johns Hopkins Hospital on February 14, 1937, complaining of bilateral ear ache. Late in December 1936, the patient contracted a severe cold accompanied by pain in the right ear. Soon pain developed in the left ear, and a bilateral paracentesis was done. Then the ears drained profusely. Drainage continued until February 10, 1937, at which time a severe chill occurred and the patient became quite ill. Four days later, he came to the Johns Hopkins Hospital. His temperature at this time was 105° F. On physical examination a profuse, bubbly, pulsating discharge was noted in both external auditory canals, and both ear drums were found to be perforated. There was no mastoid tenderness. His neck was stiff and his hearing poor. A roentgenogram showed clouding of the right mastoid cells. A simple bilateral mastoidectomy was performed. Following the operation 16 grams of sulphanilamide were given by the subcutaneous route, and sulphanilamide tablets grains 5 q 4 hours were started. The culture of the pus from the mastoid region showed Beta hemolytic streptococci. The immediate postoperative course of this patient was favorable. Upon the tenth day after operation, the boy's temperature became definitely elevated. A roentgenogram did not show evidence of osteomyelitis. Because of a continuation of fever, the left mastoid region was again explored on February 27, and exuberant granulation tissue was removed. The lateral sinus appeared normal. The fever, however, continued. The sulphanilamide was increased to grains 10 q 4 hours. A sulphanilamide blood level of 9 milligrams per cent was reached and maintained. Because, however, of continuation of fever, the petrous portion of the left temporal bone was explored on March 11 and 27, 1937. Following the last operation the patient became nauseated, and the drug was discontinued on March 30. By April 1, only a trace of sulphanilamide was found in the blood. Stiffness of the neck was again noted on March 31. A lumbar puncture showed a cloudy fluid containing 5,950 white

blood cells A culture of the spinal fluid showed Beta hemolytic streptococci Intensive sulphanilamide therapy by the subcutaneous and intrathecal routes was begun on April 1 The details of this therapy are shown in chart 5 Despite all therapeutic efforts, the child died on April 8

Autopsy The gross specimen of the brain was described as follows "The cerebral hemispheres show only a few little gray patches in the meninges There are definite streaks of exudate along the fissures of Sylvius on each side In the region of the cisterna magna, and over the inferior surface of the cerebellum, there is an extensive meningitis The exudate extends up around the lateral and on to the dorsal surface of the pons The lateral and third ventricles are a little widened, and contain a purulent exudate On section no abscesses are found" Bacteriological cultures of the exudate yielded Beta hemolytic streptococci

The method of therapy in this patient's case is shown in chart 1

Case 4 J E B Sydenham Hospital, Baltimore City Health Department A three year old white boy entered the hospital on March 25, 1937, because of measles and pncumonia His older brother and sisters had had measles On March 18, the patient developed a cold, followed on the next day by a typical mcasles rash Three days later, the child had difficulty breathing, a physician was called, and a diagnosis of pneumonia was made The boy was removed to the hospital Upon admission, he showed a fading measly eruption, no Koplik spots, and dullness and crepitant rales over the right lung field Within a week after entry in to the hospital, the child had made a marked improvement However, on April 7, his ears drained spontaneously, and a spiking fever appeared This continued and because of a secondary anemia, he was given two transfusions of 100 c c of citrated blood on April 26

and 27 Just prior to the transfusions, on April 22, the child's red blood cell count was 3.2 millions, and his hemoglobin 52 per cent. He did not improve following the transfusions, and on April 26, it was noted that his neck was stiff. A lumbar puncture was performed, and gram positive diplococci were seen in the stained film of the cerebrospinal fluid sediment. The subsequent course of the patient is shown in chart 3.

CHART III

Case 4

| Date April 1937 | Sulphanilamide Therapy (grams) | | | Cerebro-Spinal Fluid | | Remarks |

In reviewing the events in the histories of these four patients, it is evident that the first patient was moribund upon entry into the Harriet Lane Home and was beyond all therapeutic aid. The second patient represents a definite failure of sulphanilamide therapy for which we have no adequate explanation. It has been our experience that hemolytic streptococcal otitis media is very responsive to treatment with this chemical. This is also true of the postoperative course of patients ill with acute hemolytic streptococcal mastoiditis, in whom sulphanilamide therapy has been instituted. However, in this instance there was a definite progression of the streptococcal infection despite supposedly adequate therapy with sulphanilamide. Whether the discontinuance of the drug on March 30 permitted the streptococci to invade the spinal fluid is a matter of conjecture, but it is interesting to note that within 36 hours the first signs of meningitis appeared, and at that time less than 1 milligram per cent of sulphanilamide was present in the blood of the patient. However, the institution of adequate therapy did not influence the course of the disease despite the fact that the streptococci isolated from this patient were susceptible *in vitro* to the bacteriostatic effects of sulphanilamide.

The record of the third patient definitely demonstrates what may happen if therapy is discontinued too soon. In this instance, on the fourth day after treatment was stopped, the meningeal invasion took place. The effect of not adding base to the sulphanilamide therapy is also beautifully illustrated in this case, by the drop in the CO_2 combining power to 15.5 volumes per cent after 111 hours of treatment. Then with intensive alkali therapy, a normal CO_2 combining power was soon reestablished.

The final case is of importance in showing the effect of neglecting specific therapy in the presence of a hemolytic streptococcal otitis media. This patient also illustrates the rapid and uneventful course to recovery that is being increasingly noted in hemolytic streptococcal meningitis since the introduction of sulphanilamide therapy.

In addition to these recorded cases of hemolytic streptococcal meningitis, we have been consulted in regard to nine other patients ill with this disease, eight of whom have recovered. Thus, from our own experience and that recorded in the literature, we have knowledge of 28 cases of streptococcal meningitis occurring within the last 16 months. All were treated with sulphanilamide or its derivatives. Twenty-four or 85 per cent recovered. This recovery rate is to be contrasted with a case fatality rate of 99 per cent before sulphanilamide therapy was used in hemolytic streptococcal meningitis. This constitutes irrefutable evidence of the value of sulphanilamide therapy in the treatment of severe Beta hemolytic streptococcal infections in human beings.

THE TOXIC MANIFESTATIONS OF SULPHANILAMIDE AND ITS DERIVATIVES

Sulphanilamide is a toxic chemotherapeutic agent, and its widespread employment will result in many fatalities unless the tendency towards its careless and reckless use is checked. Already fatalities attributed to the use of sulphanilamide or its derivatives have been reported⁵¹ and we have seen one instance in which death was associated with a toxic effect of sulphanilamide.

The most serious toxic manifestations of sulphanilamide therapy are those associated with the blood or hematopoietic system. We have seen seven patients who developed acute hemolytic anemias characterized by a sudden fall in the hemoglobin and red blood cell count, and the appearance of macrocytosis, anisocytosis, poikilocytosis, elevated white blood cell counts, nucleated red blood cells and large numbers of reticulocytes in the peripheral blood. Six of the seven patients were definitely jaundiced, and in all a marked urobilinuria was present. All of these patients recovered promptly, but in five the anemia was so severe as to necessitate one or more transfusions.

The mechanism of the production of these anemias is as yet unknown, but it does not seem to be of the nature of a true idiosyncrasy because in two of the recovered patients the subsequent administration of test doses

of sulphanilamide did not result in any change in their red blood cells. Also, there has been no correlation between the amount of sulphanilamide administered and the development of anemia. It is probable that the anemias represent an abnormal susceptibility on the part of the red blood cells of certain individuals to severe hemolysis by sulphanilamide.

Another severe toxic effect of sulphanilamide has been the development of granulocytopenia. Plumer⁵² has reported a patient who developed this toxic manifestation while under treatment with sulphanilamide. Despite the discontinuance of the drug, the patient died. In two instances Trumper⁵³ has seen definite leukopenias associated with a depression of the myeloid elements appear in patients who were being treated with sulphanilamide and "Prontosil Solution". We have seen one patient in whom death was associated with a granulocytopenia combined with a bilateral, lateral and cavernous sinus thrombosis. During the month before death, this patient had received irregular medication with "Prontosil Solution" and sulphanilamide. Recently, we have observed a patient who had made a rapid recovery from a gonococcal urethritis and arthritis as the result of sulphanilamide therapy. At the end of the third week of treatment he developed weakness, slight jaundice and a sore throat. Upon reentry into the hospital he was found to have a mild anemia and a leukopenia associated with a marked depression of the myeloid elements. An extensive angina was present. No specific therapy was used and within 10 days the patient's blood picture was normal. He was then given two test doses of sulphanilamide, the first 0.3 gram, the second 2.0 gram by mouth, without showing any depression of his white blood cells. It seems, from this lack of response to the test dose, that the mechanism of the production of granulocytopenia by sulphanilamide differs from that by amidopyrine.

In addition to the severe toxic manifestations just described, sulphanilamide produces certain mild clinical toxic effects. In normal human beings, the ingestion of 50 grains of sulphanilamide is followed in six hours by slight dizziness and mild nausea. Ambulatory patients who are suffering from streptococcal or gonococcal infections often complain of dizziness, anorexia, nausea and sometimes of a sensation which is described as being similar to that experienced when mildly intoxicated with ethyl alcohol. These effects, however, are rarely noted in patients who are kept in bed during the period of therapy.

Practically every patient who receives sulphanilamide in therapeutic doses shows a fall in the CO_2 combining power of the blood. We have seen four cases of clinical acidosis, characterized by air hunger, and a very alkaline urine without ketonuria, which have developed in the course of sulphanilamide therapy. This toxic manifestation of the drug has been studied in the medical clinic of the Johns Hopkins Hospital by Southworth⁵⁴ who noted that a variable but consistent drop in the CO_2 combining power of the blood plasma occurred in 15 consecutive cases of streptococcal infec-

tion which had been treated with sulphanilamide. We have found that this fall in the CO_2 combining power of the blood plasma is associated with an absolute loss of sodium and potassium in the urine. This loss of base varies markedly in different individuals. Certain patients have a mechanism that permits them to control this loss of base before they develop a clinical acidosis. The exact method of the control of this excretion of base during sulphanilamide is under study at the present time. We have found that the administration of 10 grams of bicarbonate of soda with each dose of sulphanilamide is of value in preventing the fall in the CO_2 combining power, and at the present time we administer bicarbonate of soda routinely with each dose of sulphanilamide.

If acidosis should develop, the administration of 1/6 molar sodium lactate solution by the intravenous and subcutaneous routes is of definite value in combating this toxic manifestation of sulphanilamide therapy. In babies, frequent small hypodermoclyses of 1/6 molar sodium lactate solution may be used to prevent acidosis.

Sulphanilamide may cause fever. When this occurs, it is best to stop the drug for two or three days during which period the temperature will fall to normal if the fever is due to the sulphanilamide therapy.

We have carefully studied the urine of patients receiving sulphanilamide without noting signs of renal irritation. As we have stated previously, sulphanilamide is not excreted rapidly by the damaged kidney, and hence it tends to accumulate in the blood of patients having decreased renal functions. We believe that if the drug is to be used in patients with decreased renal function, the sulphanilamide blood levels should be followed daily. When the blood sulphanilamide level reaches 15 to 20 mg per cent, the drug should be stopped.

Schwentker⁴⁵ and ourselves have noted morbilliform skin rashes accompanied by fever, which appeared in the course of sulphanilamide therapy. These rashes generally develop from the eighth to fourteenth day of treatment. When such skin eruptions develop, sulphanilamide therapy should be discontinued, and the rash and fever will disappear within 48 hours.

In patients suffering from the acute toxic manifestations of sulphanilamide therapy, we have found that large amounts of fluids act as an antidote. We have seen one patient who took 12 grams of sulphanilamide within 12 hours and who developed headache, dizziness, nausea and a moderate degree of cyanosis. Inasmuch as we know that the chemical is excreted with water, we had this patient force fluids to the extent of taking 5,000 cc of water by mouth within a six hour period. The drug was rapidly excreted, and after a few hours, all signs of toxicity disappeared.

Colebrook and Kenny³ reported that the "Prontosils" had a mildly irritative effect upon the kidney, and that these compounds produced sulphemoglobinemia in three of their patients. They believed, however, that the association of saline cathartics with the therapeutic administration of the

"Prontosils" was a contributing factor in the production of the sulphemoglobinemia, and advised against the use of saline cathartics in patients receiving "Prontosil"

In our experience "Prontosil Solution" has produced but one toxic effect, namely, fever. This manifestation appears constantly in those normal subjects who have been tested with a single large dose (100 cc) given by the subcutaneous route. It also occasionally is seen on the third day or later of continuous "Prontosil Solution" therapy. It is our practice to discontinue "Prontosil Solution" if fever appears which is considerably out of proportion to the general clinical condition of the patient. As this generally occurs at a time when the streptococcal lesion is rapidly regressing, the clinical problem is not difficult. We have not seen any evidence of renal irritation in patients receiving "Prontosil Solution."

METHODS OF ADMINISTRATION OF SULPHANILAMIDE OR ITS DERIVATIVES

Our experience leads us to believe that sulphanilamide per os is the drug of choice. If, however, the patient cannot swallow tablets, or oral administration of sulphanilamide is not desirable, we use either "Prontosil Solution" or an 0.8 per cent to 1 per cent solution of sulphanilamide in sterile physiological saline solution. These solutions are given parenterally by the subcutaneous route.

In our previous communication⁵ we came to the conclusion based on our knowledge that a 1-10,000 concentration of sulphanilamide was definitely bacteriostatic in vitro, that this would constitute an effective therapeutic level in vivo. Our earlier system of dosage was, therefore, based upon amounts of sulphanilamide which would theoretically give us this concentration.

Recently, Dr. E. K. Marshall, Jr., and his associates^{56, 57} have described a simple biochemical method for the quantitative determination of sulphanilamide in body fluid. They have noted, following a single oral dose in human beings, that the drug is absorbed in about four hours, and that a maximum concentration is reached in the blood stream within four to six hours. They demonstrated that the drug is almost wholly excreted in the urine and that this is accomplished rapidly by the normal kidney. In patients with decreased renal function, Marshall found a diminished ability to excrete sulphanilamide, and noted that the continued ingestion of the chemical in these patients resulted in an accumulation of the drug in the body. It was also noted that the drug rapidly passed over into all body fluids in approximately the same concentration as was found in the blood. These observations have been of the greatest importance in establishing a rational basis for therapy in infected human beings.

Therefore, in patients ill with very severe infections, such as hemolytic streptococcal meningitis, peritonitis and septicemia, or in meningococcal meningitis or septicemia we believe that because of the gravity of the prog-

nosis in such diseases, one should disregard all possible toxic effects of sulphanilamide or its derivatives in an attempt to control the infections as rapidly as possible. This we do by administering a large initial dose of sulphanilamide with the aim of attaining a blood level of 10 mg per cent within four hours. In adult patients, i.e. those weighing 100 pounds or more, we administered an initial dose of from 10 to 16 five grain tablets. This initial dose should give a blood level of about 10 mg per cent within four hours. Then, to maintain this level, we advise using three 5 grain tablets every four hours. If the patient weighs 50 to 90 pounds, the initial dose should be 6 to 10 five grain tablets followed by two or three tablets at four hour intervals. In children weighing from 25 to 50 pounds, four to six 5 grain tablets constitute the initial dose, followed every four hours by doses of one or two 5 grain tablets. Patients excrete the drug at slightly different rates, so the maintenance dose may vary somewhat.

We have found it advantageous to determine the blood sulphanilamide level four hours after the initial dose. If the blood does not show the expected level of 8 to 10 mg per cent, this is evidence of faulty absorption, and the parenteral administration of the chemical should be instituted. It is of value to check the blood sulphanilamide level 24 hours after therapy has been started, to determine the adequacy of the maintenance dose of the drug.

The preparation of sulphanilamide for parenteral use is simple. This chemical is soluble up to 1 per cent in physiological saline solution at 37° C. It is our practice to bring the required amount of sterile physiological saline solution to a boil. It is then removed from the flame, and as soon as it stops boiling, 0.8 to 1 gram of sulphanilamide is added for each 100 c.c. of physiological saline solution. The hot saline solution is then agitated to facilitate the solution of the sulphanilamide, cooled to 37° C. and is administered by hypodermoclysis. A 1 per cent solution of the drug will remain fairly stable if kept at room temperature. If the temperature falls, or if the solution is placed in an ice box, the sulphanilamide crystallizes out of solution. It is our custom to make up the daily requirements of sulphanilamide solution for a patient each morning.

Our experience in the use of parenteral sulphanilamide solution leads us to believe that the following amounts represent adequate therapeutic doses. In adults, the initial hypodermoclysis should be 500 c.c. of a 1 per cent solution, followed by 300 c.c. at eight hour periods during the first 24 hours. The initial dose for individuals weighing from 50 to 90 pounds should be from 200 to 400 c.c. followed by 200 c.c. at eight hour intervals. Children weighing 25 to 50 pounds should receive an initial dose of 100 to 300 c.c. of sulphanilamide solution, this to be followed with 100 to 200 c.c. of the solution at eight hour intervals. In babies, it is difficult to determine the dose, but they should receive a total of 1 gram of sulphanilamide per 10 pounds of body weight during the first 24 hours.

Sulphanilamide solutions may be given by the intrathecal route in the treatment of streptococcal infections of the meninges. The drug has not been found irritating to the meninges, and the technic of administration is the same as that used in giving antisera by this route. The solution is warmed to 37° C and after the spinal drainage has been completed, an amount of sulphanilamide solution equivalent to 5 or 10 c c less than the amount of cerebrospinal fluid which has been removed, is permitted to run into the spinal canal under the force of gravity. Never inject the solution under *positive pressure*. Intrathecal therapy may be given at eight hour periods in infections of the meninges.

"Prontosil Solution" should be given by the subcutaneous route. It is absorbed rapidly and is practically non-irritating. For two or three minutes after its injection, a sensation of burning or stinging may be noted at the site of injection. This may be obviated by infiltrating the area of injection with a small amount of a local anesthetic. The drug is absorbed rapidly, and has been noted in the urine within 15 minutes after a single subcutaneous injection of 100 c c of the solution. Because of the frequency with which the drug is given, we start its administration in the right pectoral region and proceed to the left pectoral region, then to the outside, top and inside of both thighs, and next to each of the buttocks. Following the injection in the buttocks, one may return to the right pectoral region.

In adults, the therapeutic dose of "Prontosil Solution" is 20 c c at four hour intervals or a total of 120 c c of the solution in 24 hours. Individuals weighing 50 to 90 pounds should receive from 10 to 15 c c of the drug at four hour intervals. Children weighing from 10 to 50 pounds should receive 5 to 10 c c every four hours. These doses should be continued in each instance until a definite clinical effect has been obtained. Then the dose may be gradually decreased. It will be noted that doses of "Prontosil Solution" such as we have recommended will color the skin pink and the urine bright red. "Prontosil Solution" is definitely irritating when given intrathecally, and should not be administered by this route. Severe reactions may occur after the intravenous administration of the drug.

After definitely favorable clinical effects in the patient have been obtained, the dose of sulphanilamide should be rapidly decreased. At first, the dose may be cut by one-third. Then if the improvement in the patient's condition is continued, the drug should be cut to one-third of the original amount. This should be continued until convalescence is well established.

Up to this point, we have discussed only the maximum dosage which is to be used in very severe streptococcal or meningococcal infections. Moderately severe streptococcal infections in adults may be controlled by the administration of three 5 grain tablets of sulphanilamide at four hour intervals. Mild streptococcal infections may be combated with one or two tablets at four hour intervals. In children, one or two tablets every four hours constitutes an effective dose. As soon as a definite clinical improvement is

noted, the amount of sulphanilamide should be decreased. If a recurrence of the infection occurs, or if clinical improvement is not seen after 36 hours of sulphanilamide therapy, the therapeutic dose of this substance should be increased.

Sulphanilamide can be used as a prophylactic agent in the prevention of streptococcal infections, especially in the face of epidemic outbreaks. In adults two 5 grain tablets three or four times a day constitute the prophylactic dose, while in children one tablet three times a day appears to be sufficient.

SUMMARY

1 Clear experimental and clinical evidence is available which leads us to believe that sulphanilamide and its derivatives constitute powerful chemotherapeutic agents in the treatment of hemolytic streptococcal infections.

2 Experimental and clinical data support the use of sulphanilamide in meningococcal infections.

3 The clinical results obtained in treating gonococcal infections have been favorable.

4 Sulphanilamide has certain serious toxic effects upon the hematopoietic system.

5 The careless and reckless use of sulphanilamide is unwarranted, and will undoubtedly result in fatalities.

We wish to thank Dr E A Park, Dr Frances F Schwentker and Dr Herbert Harms for their courtesy in making the records of certain patients available to us.

The "Prontosil Solution" used in these experiments was supplied by the Winthrop Chemical Company. The sulphanilamide was supplied by the Abbott Laboratories, Lederle Laboratories, Merck and Company, Inc, E R Squibb and Sons, the Myron L Walker Company and the Winthrop Chemical Company.

THE HEREDITARY FACTOR IN ESSENTIAL HYPERTENSION ~

By EDGAR A. HINES, JR., M.D., F.A.C.P., *Rochester, Minnesota*

EVEN before facilities were available for measuring the blood pressure it was observed that vascular disease occurred with unusual frequency among members of some families. In 1769, Morgagni recorded cases of apoplexy and said that he believed the condition was influenced by hereditary factors in these cases because many near relatives of the patients had been afflicted with a similar ailment. In 1872, Gull and Sutton reported a group of cases of chronic interstitial nephritis and expressed the opinion that the disease in these cases was due to an arteriocalillary fibrosis throughout the body rather than the result of a lesion in the kidneys. They commented on the hereditary nature of the disease in this group of cases. Janeway, in 1916, wrote "The belief in an inherited quality of the arterial tissue with a tendency to premature death from apoplexy, angina pectoris and other local manifestations, is too firmly grounded in clinical observation to be without basis. Hypertensive arterial disease must be looked on to-day as the type in which heredity plays the largest rôle." These conclusions were derived mainly from scattered reports of human pedigrees and from casual clinical observations. It is only within the past 15 years that investigations of this problem have been of sufficient scope to be of significance.

The problem of the hereditary factor in hypertensive disease has been studied for the most part by three methods: (1) by observing and recording the histories of families in which vascular disease or hypertension has affected many members, (2) by investigating the family history as to the incidence of hypertensive cardiovascular disease among those who have or have had hypertension or a normal blood pressure, (3) by a study of the blood pressure of members of hypertensive and nonhypertensive families.

Weiss, Rosenbloom, Waldbott, Ayman and Étienne and Richard have studied the history of two or more generations of certain families in which an elevated blood pressure was found among a large number of the members. Ayman's report is especially significant as the blood pressure of three generations (32 members) of one family was measured.

Janeway obtained a history of familial cardiovascular disease from 50 per cent of a group of patients with hypertension. Popper studied 1,031 cases of hypertension and concluded that the hereditary factor was important. In studying the significance of an elevated blood pressure among young persons, Frost obtained a positive family history of cardiovascular disease from 28 per cent of 400 young adults who had an elevated blood pressure. Barach, in an especially detailed study of a small group of cases

* Presented at the St. Louis meeting of the American College of Physicians, April 20, 1937.

From the Division of Medicine, The Mayo Clinic, Rochester, Minnesota.

of hypertension obtained a family history of cardiovascular disease in 95 per cent. He called attention to the incomplete information obtained from the family histories taken in the routine manner. I have found this to be true and in many instances have secured additional information by detailed questioning. A general question as to whether the patient knows of any hypertension or cardiovascular disease among his relatives elicits poor information. A direct question concerning the state of the blood pressure, heart, kidneys and cerebrovascular system of each near relative will result in a surprising amount of additional information.

Data concerning the incidence of hypertensive cardiovascular disease among relatives of persons who have hypertension and relatives of persons who have a normal blood pressure are of more significance than are similar data concerning only the relatives of persons who have hypertension. O'Hare, Walker, and Vickers found that 68 per cent of 300 patients who had hypertension gave a family history of cardiovascular disease, as compared with 37 per cent of 564 patients who did not have hypertension. They concluded that heredity undoubtedly plays one of the most important rôles in the production of hypertensive disease. Glomset measured the blood pressure of 2,400 school children and found a positive family history among 39 per cent of the children who had an elevated blood pressure and among 10 per cent of the children who had a normal or low blood pressure.

Since medical information concerning relatives usually is incomplete, measurement of the blood pressure of relatives gives more reliable information than does a study of the family history. Weitz has measured the blood pressure of brothers and sisters of hypertensive and nonhypertensive persons. He found that the incidence of elevation of the blood pressure was significantly higher among siblings of persons who had hypertension than it was among siblings of persons who did not have hypertension. The most extensive and significant study of this type has been made by Ayman². He studied the blood pressure of 1,524 members of 277 families and found that in the families in which both parents had absolutely normal blood pressures the incidence of elevated blood pressures among the children was only 3 per cent. In the families in which one parent had arteriolar hypertension the incidence rose to 28 per cent and in families in which both parents had arteriolar hypertension the incidence was 45 per cent. Ayman found that the so-called emotional hypertension of young adults occurred almost wholly among the children of hypertensive families. He confirmed Weitz' studies in regard to the higher incidence of elevated blood pressure among siblings of persons who had essential hypertension.

RATIONALE OF PRESENT STUDY

Previous investigations of the hereditary factor in essential hypertension have been unavoidably deficient because high blood pressure becomes evident at varying ages, usually in later adult life, and because many persons

who have essential hypertension have frequent periods during which the blood pressure will be found to be normal. The emotional stimulus of taking the blood pressure often is not sufficient to cause a maximal elevation of the blood pressure or to bring out a latent hypertension. This can be demonstrated by a comparison of the blood pressure obtained at the first examination and that taken after the application of a strong external, sensory stimulus, such as ice water. I have collected a group of 90 cases in which there were hypertensive changes in the retinal arterioles, in these cases the values for the blood pressure, which was taken in the office, were always less than 150 mm of mercury for the systolic pressure and 95 mm for the diastolic pressure and frequently were normal or low. On application of a cold stimulus the value for the blood pressure would increase from 20 mm to 60 mm of mercury higher than the readings taken in the office. In these cases, the emotional stimulus of taking the blood pressure is not sufficient to bring out a latent hypertension. In 608 cases I have studied the blood pressure before and during the application of a cold stimulus. In 43 per cent of the cases the values for systolic and diastolic blood pressures were 10 mm of mercury higher during the application of the cold stimulus than they were on any reading before the application of the stimulus. In 8 per cent of the cases this increase amounted to 20 mm or more of mercury. In 5 per cent of the cases the initial values were less than 120 mm of mercury for the systolic pressure and less than 70 mm for the diastolic pressure but the value for the systolic pressure increased to more than 145 mm of mercury during application of the cold stimulus and the value for the diastolic pressure increased to more than 90 mm. Furthermore, it was found that from an emotional stimulus alone the elevation of blood pressure may be only in the systolic blood pressure, apparently as a result of cardiac stimulation rather than the result of vasoconstriction. Such emotional reactions of the blood pressure are of questionable significance if they are to be compared with the reactions in essential hypertension.

Hyperreactivity of certain portions of the arterial system is generally recognized as an important agent in producing the abnormality of the blood pressure which occurs in essential hypertension. A reliable method of measuring vasomotor reactivity, which does not depend on an emotional response and which would bring out a latent hypertension at each examination, should supply more complete information than has been obtained in previous studies of the hereditary factor in essential hypertension. The cold pressor test is believed to fulfill these requirements adequately.⁹ The technic of the test is as follows. The subject is allowed to rest in a supine position in a quiet room for 20 to 60 minutes. Thirty minutes is a satisfactory rest period for persons who have a normal blood pressure. If hypertension is present, a longer period of rest may be necessary to establish a basal level. Several readings of the blood pressure are taken until a basal level has been approximated. The cuff of the sphygmomanometer is placed

on one arm of the subject and his hand is placed in ice water (4°C) to a point just above the wrist. Readings of the blood pressure are taken at the end of 30 seconds and again at the end of 60 seconds. The maximal reading obtained while the hand is in the ice water is taken as an index of the response. The hand is removed from the ice water and readings are taken every two minutes until the blood pressure returns to its previous basal level. The maximal response frequently occurs within 30 seconds. The blood pressure of subjects who have a normal blood pressure returns to the basal level within two minutes. In the presence of established hypertension there

FIG 1 Response of systolic blood pressure to cold pressor test

may be a delay in the return of the blood pressure to the previous level. Sedatives and vasodilating drugs should not have been used by the patient for 24 hours before the test is performed. Observations have shown that the emotional factor does not play an important rôle in the response of the blood pressure to this test*.

The test has been used for five years in studying the reactions of the blood pressure of a large group of patients. It divides all persons into two groups: (1) Those who have minimal or "normal" reactions, and (2) those who have excessive or "abnormal" reactions. When the reactions to

* Unpublished data in thesis, "A Clinical Test of Vasomotor Irritability: Blood Pressure Response to Cold," by Edgar A. Hines, Jr. (1933), on file in The Mayo Foundation, The Mayo Clinic, Rochester, Minnesota.

the test were compared with the effects of environment, it appeared that the test is an index of the way in which a person's blood pressure reacts to environmental stimuli. Almost all persons afflicted with essential hypertension have abnormal or excessive reactions. One group of individuals who do not have hypertension gives excessive reactions to the cold pressor test in both systolic and diastolic blood pressure. These individuals have been called "hyperreacting normals" (figure 1). In a study of 400 school children, 18.7 per cent were found to be hyperreactors to the test.⁸ It is believed that this hyperreacting state of the blood pressure of normal persons represents a prehypertensive stage of essential hypertension and that many of these persons eventually will have essential hypertension. The transition from this hyperreactive state to essential hypertension has been observed among a small number of individuals during the five-year period of observation. Because of these significant observations concerning the cold pressor test, I have used the test in a study of the hereditary factor in vasomotor reactivity and in essential hypertension.

METHOD OF STUDY

The observations have been carried out along three lines: (1) a correlation of the type of reaction to the test and the incidence of hypertensive disease in the family history, (2) a study of the reaction of twins to the test, (3) a study of the reaction of members of hypertensive and nonhypertensive families to the test.

DATA

Correlation of the Type of Reaction and the Family History. A detailed study was made of the incidence of hypertensive cardiovascular disease among relatives of 492 "normal reactors" and 116 "hyperreactors." The results were compared with the family history of hypertensive cardiovascular disease in a group of 267 cases of essential hypertension. The results are shown in table I. From this table, it may be seen that a positive

TABLE I
Incidence of Hereditary Factor Among Hypo- and Hyperreactors and Patients with Essential Hypertension

| | Number | Family history of hypertensive cardiovascular disease, per cent |
|---------------------------------------|--------|---|
| Subjects with a normal blood pressure | | |
| Hyporeactors | 492 | 17.2 |
| Hyperreactors | 116 | 84.2 |
| Subjects with essential hypertension | 267 | 86.6 |

family history of hypertensive cardiovascular disease is five times more frequent among hyperreacting normals than it is among persons who have a

normal blood pressure and give a normal reaction to the cold pressor test. Also, there is a close correlation between the incidence of an hypertensive cardiovascular family history among patients who have essential hypertension and persons who belong in the hyperreacting normal group.

The Blood Pressure Reaction of Twins Seven sets of identical twins and three sets of fraternal twins have been tested. In all of the sets of identical twins the response of one twin to the cold pressor test was similar to that of the other twin, whereas, in two of three sets of fraternal twins, the response was different (figure 2). One of the sets of identical twins

FIG 2 Response of the blood pressure of twins to the cold pressor test

had essential hypertension. Their basal blood pressure readings and response to the test were almost identical.

The Reaction of the Blood Pressure and Presence of Hypertension Among the Members of Hypertensive and Nonhypertensive Families Thirty families, consisting of 256 members, are included in this group. In 12 of these families there was no evidence or history of hypertensive cardiovascular disease, in 18 families there was a definite hypertensive diathesis. Blood pressure readings were made and a cold pressor test was performed on every available living member of each family and a careful inquiry was made as to the cause of death of deceased near relatives. The pedigrees of some of these families are shown in figures 3, 4, 5, and 6. In the family group shown in figure 6, I was able to make blood pressure readings and make the test on every living member of the group, which consisted of 57 members, or three generations.

C-Family (No hypertension)

E-Family (No hypertension)

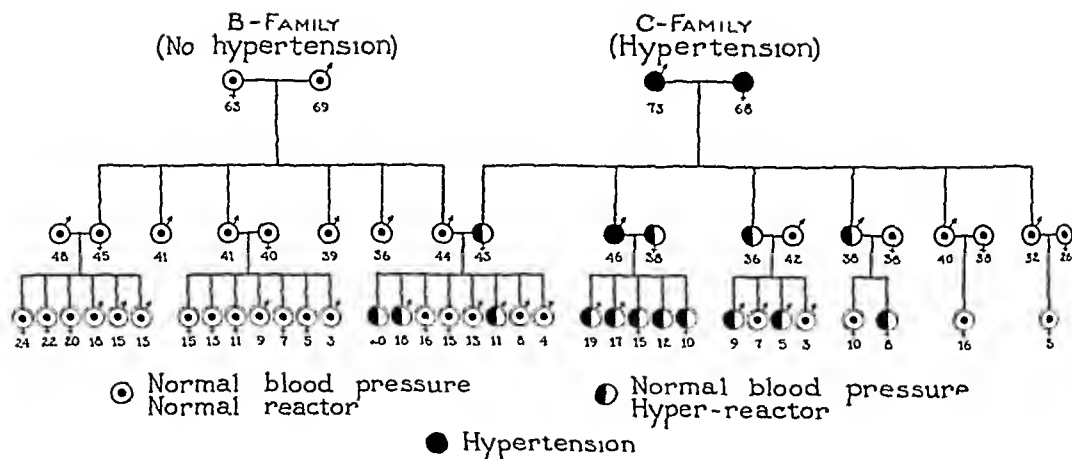

FIG. 6 Family tree showing blood pressure and response of blood pressure to cold pressor test in hypertensive and a nonhypertensive family

Investigation of these data revealed that when both parents had a normal blood pressure and were normal reactors, all of the children were normal reactors. If both parents had hypertension or were hyperreacting normals, 95 per cent of the children had hypertension or were hyperreactors to the test, and if one parent had hypertension or was a hyperreactor and the other parent was a normal reactor, 43.4 per cent of the children were hyperreactors or had hypertension. In three families of two generations, the parents had essential hypertension or had died of it and all of the children had hypertension or were hyperreactors.

SUMMARY AND CONCLUSIONS

The hereditary factor in essential hypertension has been considered. Data have been presented regarding the reaction of the blood pressure to a standard stimulus (cold pressor test) in 608 cases in which the blood pressure was "normal," in 10 pairs of twins, and in 256 members of 30 hypertensive and nonhypertensive families. A study has also been made of the family history of the 608 individuals who had a normal blood pressure and of 267 individuals who had essential hypertension. A positive family history of hypertensive cardiovascular disease is five times as frequent among individuals who have hypertension or who are hyperreactors to a standard stimulus test than it is among individuals who react normally to the test. In the study of the twins and the family groups it was found that the type of blood pressure reaction to the test followed an inherited pattern. Inasmuch as I so far have not found any hyperreactor who did not have one parent who had hypertension or was a hyperreactor, it is probable that the trait is inherited as a dominant characteristic. The excessive or "hypertensive" type of reaction occurred predominantly among members of families in which there was an hypertensive diathesis. These findings are considered

to be strong evidence that the hereditary factor plays an important rôle in the development of essential hypertension. The inherited quality may be a vasomotor system which reacts excessively to certain external and internal stimuli and eventually results in the development of essential hypertension in many cases.

FACTORS INFLUENCING THE PROGNOSIS IN DIABETIC COMA^{*}

By EDWARD S. DILLON, M.D., F.A.C.P., and W. WALLACE DYER, M.D.,
Philadelphia, Pennsylvania

IN making this report we have two purposes, first to present briefly chemical and clinical data of cases of diabetic acidosis as encountered in a large city hospital, and second to evaluate data determined at admission in regard to their effect on the prognosis.

For many years we have been impressed with the fact that both the rate of incidence and the mortality rate of acidosis are much higher in diabetics of the economic and intellectual class of society which is dependent on the city hospital than in those diabetics seen in private practice. During the six years 1931 to 1936 there were admitted to the wards of the Metabolic Division, Philadelphia General Hospital, 3009 cases of diabetes, 268 of these patients were admitted in acidosis and it is their records which form the material of this report. There were 224 individuals, as 21 patients were admitted in acidosis 44 additional times. Eleven patients were admitted in acidosis twice, four patients three times, four patients four times, one patient five times, and one patient ten times. The latter patient (No. 252) was given a job in the hospital nearly two years ago and has not been in coma during this time.

The Metabolic Division has its own trained personnel and physical equipment, consisting of two wards of 25 beds each, laboratories, diet kitchen and out-patient department, all located as a single unit. All the diabetics of the hospital are concentrated in this department regardless of complications, except cases of open tuberculosis and psychopathic patients. Without this department the diabetic patients would be scattered among ten medical services, four surgical services and numerous special services. The out-patients consist only of patients who have been discharged from the wards. As a result of the above circumstances a new patient usually is one who has come to the hospital only because of some serious complaint or complication, and who knows little or nothing about diabetes, and about whom the staff has no information. Of the 224 individual patients in this report, 82 patients did not know they had diabetes at the onset of the acidosis which caused them to be admitted to the hospital.

In a large series of uncontrolled diabetics, all degrees of acidosis occur and it is difficult to decide which cases are worthy to be included in a report. Some authors give no criteria concerning the basis of selection of the cases included in their reports. More usually the authors have selected some figure for the CO_2 volume per cent and included all cases below that figure.

^{*} Presented at the St. Louis meeting of the American College of Physicians, April 22, 1937.

The figures selected have varied widely, ranging from 15¹ to 45² Joslin³ in his seven reports has included cases of 20 and below In this report all cases have been reported in which the CO₂ volume per cent was 29 or lower The reasons for selecting this figure will be discussed later in this report

Of the 268 cases admitted in acidosis 117 died, a mortality of 43.7 per cent Some years ago, when it became obvious to us that our mortality was much larger than that reported from other clinics, we made a careful study of our records for the purpose of analyzing the causes of the high mortality and with the hope of reducing it Because of the large number of patients having serious complications, we found it necessary to separate the cases into groups and the criteria which we set up were as stated in table 1

TABLE I

Criteria Used to Group the Diseases Complicating Diabetic Acidosis

- A No complicating disease (cases recovering = AR, cases dying = AD)
- B 1 Any disease sufficient to precipitate coma in a diabetic, but not severe enough to cause death as a rule in a non-diabetic
- 2 Any disease severe enough to cause considerable mortality in non-diabetics If the case of acidosis dies, he has been out of acidosis less than 48 hours prior to death (cases recovering = BR, cases dying = BD)
- C 1 Like B₂, except that all cases die, but have been out of acidosis more than 48 hours prior to death
- 2 Any disease the mortality of which would be very high in non-diabetics in a short period of time The acidosis is merely a terminal event of the fatal disease
- 3 Any disease from which the patient dies many days after complete recovery from the acidosis

It will be noted that the certainty of a patient's having died from the complication and not the acidosis increases progressively from B₁ to C₃ in this table In general the "A" cases had no complications, the "B" cases had complications but when death occurred the chief factor was probably the acidosis, and the "C" cases all died, the complications being of such severity that all would probably have died even if there had been no acidosis

We have included as complications only such conditions as were likely to precipitate acidosis General conditions such as arteriosclerosis, latent syphilis, etc., are not included regardless of what effect they may have had on the general vitality of the patient We have not regarded anuria as a complication, but as a condition directly dependent upon the acidosis

There were 129 uncomplicated cases and 139 cases with complications In the "A" group (tables 2 and 3) 97 recovered and 32 died, the mortality being 24.8 per cent In the "B" group (tables 4 and 5) 54 recovered and 27 died, the mortality being 33.3 per cent In the "C" group (table 6) all 58 cases died, of which, however, 19 cases died many days after recovery from the acidosis In tables 7 to 15 the letters "AR" refer to cases recovering in the "A" group, "AD" to cases dying in the "A" group, "BR" to cases recovering in the "B" group, "BD" to cases dying in the "B" group, "C₁C₂" and "C₃" to cases as set forth in table 1, "R" to total cases recovering and "D" to total cases dying, following which the mortal-

ity is given. Because the 19 "C₃" cases recovered from the acidosis, the mortality has also been calculated with these cases regarded as recoveries instead of deaths, and "R + C₃" refers to total recoveries plus the "C₃" cases, and "D — C₃" refers to total deaths minus the "C₃" cases. If the 19 "C₃" cases are regarded as recoveries, the total mortality for the entire 268 cases becomes 36.6 per cent. In tables 5 and 6 the + and — signs in the "group" column indicate whether the CO₂ was above 40 prior to death.

In the 139 cases with complications there were 105 cases with infections, of which 68 occurred in the "B" group and 37 in the "C" group. The location of the infections was as follows: Respiratory system (except tu-

berculosis) 36, gastrointestinal system 14, genito-urinary 9, skin and subcutaneous tissues 16, feet 16, miscellaneous 5, pulmonary tuberculosis 9. Of the 34 non-infections, 13 were in the "B" group and 21 in the "C" group. These consisted of coronary occlusion 7, hyperthyroidism 6, acute alcoholism 4, cancer 3, apoplexy 2, hypertensive congestive failure 2 and miscellaneous 10.

Of the 117 cases which died, postmortem examinations were made in 68 cases, 58.1 per cent of the deaths. Postmortem examinations are indispensable for making accurate final diagnoses in cases dying in diabetic acidosis. When patients in acidosis are admitted with inadequate histories or no histories at all, and die without coming out of acidosis, the presence of complications, their nature and severity often can only be guessed at, and not infrequently they are missed entirely unless postmortem examinations are made. Recent examples of cases in which the complication was not diagnosed during life are patients 1985 (C 36), 1999 (C 37) and 2076 (C

39) The first case was a colored woman aged 49, admitted 8/5/36. She was not known to be diabetic. Her sister stated that she had been working until three days prior to admission and for three days had been extremely weak. She was unconscious at admission and died in 31 hours. At autopsy miliary tuberculosis was found. The second case was a colored woman aged 76, admitted 8/27/36. A friend stated she had been well until seven days prior to admission, since when she had been weak and compelled to stay in bed. Her friend knew she was a large water drinker but did not know whether she had diabetes. Her urine contained large numbers of leukocytes. She was unconscious at admission and died in 17 hours. At autopsy multiple abscesses of the kidneys were found. The third case was

a white woman, aged 55, admitted 11/26/36. She was rational and neither she nor her husband knew that she had diabetes. She was well until November 20 when she ate some pie which caused severe abdominal pain. On November 21 and 22 she vomited and had marked obstipation, and the next day pains in the chest. A doctor was not called until November 26. At

Among the 29 cases in the "BD" and "C₁C₂" groups in which post-mortem examinations were not made, it is quite likely that we have made some mistakes in diagnosing complications which did not exist. It is also just as likely that we missed complications in the "AD" group in the 15 cases in which there was no autopsy.

In the total number of cases there were many of unusual interest, two of which we feel deserve short descriptions. Patient 1594 (AD 25) is included in the AD group, although he died 21 days after admission. At postmortem examination no cause for his death could be found other than

lesions in his brain which we have described⁵ in other cases dying from diabetic acidosis. Patient 1255 (C 49) is diagnosed "dysinsulinism". His history strongly suggested spells of spontaneous hypoglycemia at times for a period of two years. He was admitted in diabetic acidosis and took moderate doses of insulin for three weeks. He then began to have very severe

spontaneous hypoglycemia which could not be controlled Two months after admission a laparotomy was done in the hope of finding a pancreatic adenoma None was found and part of the pancreas was resected, from which he died two days later

In estimating at the time of admission the prognosis of a case of acidosis,

first of all we should like to know what complication may be present and its severity Of the 139 cases with complications, 85 died, a mortality of 61 2 per cent As we have already pointed out, it often happens that no judgment can be formed as to the part a complication is playing until after the patient has been under treatment a considerable period of time, and the very presence of a complication may not be suspected until the postmortem ex-

amination. It is only in cases in which the complication is fairly evident at the time of admission that the question of a complication can be given much consideration in estimating the prognosis. Our procedure in this report has been to group the cases according to the outcome of the cases, and then to examine the data which were known within the first hour after admission in order to estimate what inference regarding prognosis may be drawn from each datum.

Blood Sugar (table 7). The degree of hyperglycemia is not usually considered to have much effect on mortality. Certainly no one believes that diabetics die from high blood sugar. But when the blood sugar is very high the factors which do cause death are more likely to be present. The mortality for all the cases in which the blood sugar was above 700 was

57.7 per cent, whereas for the cases for which it was 400 or lower, it was 29.1 per cent. If the "C₃" cases be regarded as recoveries, the mortality was 52.0 per cent and 21.8 per cent respectively, about two and one-half times as high in the high blood sugar group as in the low one. Among the uncomplicated cases it may be pointed out that the average blood sugar in the "AR" group was 487, and in the "AD" group 713. When the blood sugar is very high, therefore, we are justified in anticipating a higher mortality than when it is low.

We have previously published ⁴ 16 cases in which the blood sugar was 1000 or above, the first case occurring in 1925. We now add nine additional ones (table 8). Of the total of these cases nine recovered and 16 died. Case 10 does not appear in tables 2 to 6 as she arrived in the receiving ward moribund and died a few minutes after her blood had been taken and sent to the metabolic laboratory. Case 14 had a blood sugar of 1850,

the highest in the literature in which recovery occurred Cases 22 and 23 are the same individual, a white man aged 45

CO₂ Volume Per Cent (table 9) The degree of chemical acidosis is measured by the CO₂ combining power measured in volumes per cent As might be anticipated, the mortality is higher the lower the CO₂ This becomes clear, however, chiefly in the uncomplicated cases The presence in the total series of a large number of cases with severe complications masks the effect of the acidosis

In determining a criterion of acidosis according to which the selection of cases for this report might be made the level of 29 volumes per cent CO₂ was selected for the following reasons The unusual figure 29, instead of some multiple of five or ten, comes about by virtue of the fact that many years ago our laboratory began to keep its CO₂ files in groups of 10, 60 to 69, 50 to 59, etc We feel justified in including the group 20-29, because in this group out of 109 cases there were 47 deaths, in seven of which no other cause of death was found

At the low extreme our chemists have reported no value lower than six The analyses are made routinely within 20 minutes after the blood is withdrawn When the observed volume of gas is very low, in addition to technical difficulties is the fact that the corrections become larger than the final result, and therefore of relatively great importance The chief difficulty, however, is that when the CO₂ combining power is as low as 2 volumes per cent, as reported by several observers, the corresponding alveolar CO₂ tension, at a pH compatible with life, should require a ventilation rate of approximately 40 liters per minute in order to rid the body of the CO₂ of metabolism This is a matter for the chemists to settle, and from the clinical point of view is only of academic interest

Blood Urea Nitrogen (table 10) The effect of an abnormal blood urea nitrogen is more striking than either an increase in blood sugar or a decrease in CO₂ As the blood urea nitrogen increases above 20 mg per cent the mortality increases rapidly In the total series the mortality for cases with 20 mg and below was 22.1 per cent, whereas for those cases with more than 20 mg the mortality was 62.4 per cent This increase in mortality is also clearly seen in the uncomplicated cases, being 8.3 per cent for the cases of 20 mg and below, and 41.5 per cent for the cases of 21 mg and above The average blood urea nitrogen in the "AR" cases was 20.5 mg per cent and the average in the "AD" cases 44.7 mg per cent

Leukocytosis (table 11) In 77 cases the white blood count is not included in this report, either because it was not done or because it was not done until some hours had elapsed after treatment was begun The white count usually drops rapidly as treatment progresses In the 191 cases in which a white count was made at admission it is noteworthy that it was above 10,000 in all but 16 cases There is no correlation between the degree of leukocytosis and the mortality More important is the fact that the

degrees of leukocytosis seem to be about the same for the uncomplicated cases and for those in which complications are present. Even when the leukocytosis is marked, it does not add to the evidence in favor of a complication. There were 19 cases with white counts above 40,000 of which nine were uncomplicated and 10 had complications, which is almost exactly the ratio of complicated-uncomplicated cases in the entire report (129 to 139). The two highest counts were on patients 1827 (AR 83) 72,100 and patient 287 (BD 8) 73,200.

Age (table 12). The increase in mortality with advancing years is very striking. This increase is due in part to the larger amount of death-dealing complications which begin to appear at about age 40, and in part to the inability of older patients to withstand the acidosis itself. The total mortality for patients up to 30 years was 16.4 per cent while for those over 50 years it was 74.7 per cent, with the "C₁" cases regarded as recoveries, 13.6 per cent and 62.0 per cent respectively. Of the "A" cases 30 years of age and under, 67 recovered and nine died, of these nine, seven were unconscious when admitted and six had been in acidosis over 24 hours. On the other hand, of the cases over 50 years of age 10 recovered and 13 died. The average age for the "AR" group was 27.1 years and for the "AD" group 41.8 years. The average of all 268 cases was 37.8 years.

Sex and Color (table 13). There are 81 males and 187 females in this series, the total mortality being 29.6 per cent for the males and 49.7 per cent for the females. In the uncomplicated cases the mortality is only a little larger for the females. In the "BD," "C₁C₂" and "C₁" groups, however, there are 71 females and only 14 males. This disproportionately larger number of females is hard to account for. It is not due to diseases of the female organs. It is our impression that the presence of this great number of serious complications in women is due to greater negligence and less willingness to go to a hospital until driven to it. Our experience with our entire clinic, however, is that once in the hospital the women are more anxious to stay on than the men.

The population of Philadelphia is 11.3 per cent colored and the patients admitted to the metabolic division are approximately 20 per cent colored. In this report there are 166 white cases in 144 patients and 102 colored cases in 80 patients. The incidence of acidosis is, therefore, about two and one-half times as great in our colored patients. The mortality, however, is somewhat lower in the colored, but this is mostly accounted for by the greater percentage of return cases. Of the 44 return cases, 22 are white and 22 colored, two white cases died and one colored.

Mental State (table 14). The cases have been divided into conscious and unconscious groups, according as to whether it was possible to arouse them sufficiently to answer "Yes" or "No" to some simple question. The importance of the mental state in the prognosis is very great. The total mortality for the conscious patients was 28.0 per cent and for the uncon-

scious patients 81.0 per cent, with the "C₃" cases regarded as recoveries 19.0 per cent and 78.5 per cent. In other words a conscious patient is about four times as likely to recover from the acidosis as an unconscious one. In the uncomplicated cases, only 5.4 per cent of the conscious cases died whereas 73.0 per cent of the unconscious cases died.

Hours in Acidosis (table 15). We have been able to tabulate the cases according to the duration of the acidosis only in general terms. Even if an accurate history is available, when, from the history alone, may a patient be said to begin to be in acidosis? We have taken as our criterion the onset of nausea and vomiting, or when this symptom was not mentioned in the history or not present, we have taken the statement that the patient definitely became drowsy. In 67 cases it was impossible to make any estimation. According to the duration of the acidosis the cases have been divided into four groups: (1) Up to 12 hours, (2) 13 to 24 hours, (3) 25 to 48 hours, and (4) 49 hours and above. As might be expected the mortality increases rapidly with the duration of the acidosis as shown in table 15.

There are, of course, other important clinical data which aid in estimating the prognosis, chief of which is the state of the cardio-vascular system. When the blood pressure is very low at admission or falls during the course of treatment, this is of very evil omen. We have not been able to present this in the form of a table. Of great importance, also, is the rapidity with which a patient responds to treatment. We are confining ourselves in this report, however, to the data which are available during the first hour after admission.

It is obvious from the above data that a much more accurate prognosis can be given from the clinical data than from the laboratory data. In estimating the prognosis of a given patient or in comparing the mortality of one series of comas as compared with some other series, it is far more important to know the complications present, the mental state, the age of the patients, and the duration of the acidosis, than it is to know the blood sugar, the CO₂, and the urea nitrogen. As regards treatment, however, frequent estimations of the blood sugar and CO₂ during the course of the acidosis are indispensable in properly gauging the doses of insulin and glucose.

HYPERTHYROIDISM IN THE NEGRO *

By WILLIAM B PORTER, M D , F A C P , and HARRY WALKER, M D ,
Richmond, Virginia

A REVIEW of current literature and monographs which deal with diseases of the thyroid gland gives definitely the impression that hyperthyroidism is uncommon in the negro ^{1, 2} We have been impressed with the fallacy of this current belief From the files of the St Philip Hospital † for negroes we have selected records of 37 patients admitted during the past five years which justify an unequivocal diagnosis of Graves' disease

Twenty-seven of the patients lived in the city of Richmond and the remaining 10 in the adjoining counties, this entire section of Virginia is geographically a tidewater area and is distinctly a non-endemic goiter zone

Throughout the period of this study we have been impressed with the fact that hyperthyroidism in the negro is invariably definite and characteristic in its clinical manifestations The symptoms begin abruptly, invariably pursue a progressive course with increasing intensity, spontaneous remissions rarely if ever occur, and iodine induced remissions are of brief duration

Regardless of age, the clinical behavior of the patients and the observed physical phenomena were characteristically typical of the Graves' syndrome (figure 1) In only one patient was there made the diagnosis of thyroid adenomata with hyperthyroidism In the remaining 36 patients the clinical picture was that of exophthalmic goiter That this clinical impression was correct is substantiated by the histologic changes observed in the glands removed surgically Thirty-three of the 34 specimens showed varying degrees of diffuse hyperplasia

In addition to the usual symptoms and signs observed in Graves' disease, others of peculiar interest are frequently present in negro patients The most characteristic and constant phenomena occurring in the finger nails are illustrated in figure 2 The nails are brittle and thin, but stiff, and, when the examining finger is drawn across the edge, it causes the sensation as of scraping the sharp edge of a razor blade The nails become undermined and there is a definite line of pigmentation at the point of fusion of the excavated and non-excavated portion

We have followed many of the patients after the basal metabolism was reduced to normal by a subtotal thyroidectomy and observed a disappearance of the abnormality of the nails with an improvement of general nutrition ‡

† St Philip Hospital, a part of the Hospital Division of the Medical College of Virginia,
is for negro patients only

‡ These changes occur also in the white race, but are neither so constant nor so evident

FIG 1 Illustrating our conception of Graves' disease in a negro

FIG 2 The nail changes in exophthalmic goiter Note that manicuring has not altered the basic characteristics

Pigmentation of the nails (figure 3) is frequent but by no means typical of hyperthyroidism, for it is prevalent in a variety of nutritional maladies and is occasionally present in healthy individuals

FIG 3 Pigmented nails See text

The skin is peculiarly thin, the wrinkles very fine and the texture is of a velvety quality (figure 4) The skin phenomena are best observed on the back of the hands and the flexor surface of the forearms and are strikingly

FIG 4 Note the fine texture of the skin

different from the dry coarse skin noted in other non-febrile nutritional maladies seen frequently in negro patients living in this section of the country

Twenty of the 37 patients were subjected to intensive cardiovascular study with the aid of teleroentgenograms, electrocardiograms and the usual clinical methods The data are tabulated in table 1 Of these so studied,

13, or 65 per cent showed cardiothoracic ratios greater than 50 per cent. In nine of the 13 patients who had roentgen-ray evidence of cardiac enlargement, hyperthyroidism was the only demonstrable factor responsible for the observed change. There existed neither arterial hypertension nor the phenomena of valvular disease, and all of these patients were less than 40 years of age, varying from 15 to 39 with an average age of 29 years.

Electrocardiograms were made on 22 patients (table 1). Fifteen, or

| 20 | 22 | F | +86 | 140 | 140 | 70 | 49% | Normal |
| 21 | 23 | F | +41 | 132 | 144 | 55 | Data lacking | Normal |
| 22 | 27 | F | +32 | 122 | 130 | 65 | 44% | Normal |

68 per cent showed significant deviations from the normal and in only four of these did there occur vascular or endocardial disease which could reasonably have been responsible in part for the abnormal changes

That there is a striking tendency for the heart to resume a normal functional state following relief of hyperthyroidism is clinically impressive. A study is in progress to determine whether electrocardiographic changes and cardiac enlargement disappear with the restoration of normal health

The 15 patients who were not studied either with the roentgen-ray or the electrocardiograph varied in age from 12 to 60 with an average age of thirty-four. Six of the 15, or 40 per cent, had physical phenomena indicative of cardiac enlargement. Three of these had arterial blood pressure definitely above normal: in one 180 systolic, 112 diastolic, another 200 systolic, 124 diastolic, and another 170 systolic, 110 diastolic. All in this group maintained a sinus rhythm while in the hospital and none had the physical signs of either endocardial disease or congestive heart failure

It is usually assumed that a low diastolic blood pressure is common in hyperthyroidism. In this group of patients with basal metabolic rates varying from plus 25 to plus 97 with an average of plus 51, the lowest diastolic blood pressure was 50 mm Hg,* the highest 120 mm Hg with an average of 72.05 mm Hg. The absence of striking reductions in diastolic pressure may reflect the racial characteristics of the vascular system of the negro, for it is becoming increasingly evident that hypertension occurs at a lower age level in the negro than in the white race, and that there is a much greater tendency for the disease to run a malignant clinical course

Thirty-four patients were treated surgically following a preliminary period of preparation. Lugol's solution, 30 drops a day, bed rest and phenobarbital, as a sedative when indicated, were the routine measures used during the pre-operative treatment. This was extended over an average period of 13 days. There were four postoperative deaths: one due to pneumonia, two to postoperative wound infection with a *Streptococcus hemolyticus* septicemia, and one a sudden death with the cause not definitely determined but attributed to pulmonary embolism

One patient left the hospital after refusing surgical treatment. Two patients died from hyperthyroid crisis soon after entering the hospital. The total mortality was six of the 36 cases treated, a percentage of 16.6 per cent. This is an extremely high mortality, and a detailed analysis of the deaths is instructive. The death of the two patients from streptococcus septicemia was preventable and was not related directly to the hyperthyroidism

The patient who succumbed supposedly to pneumonia two days after the operation had only five days of pre-operative iodine therapy and was operated on by a surgeon with very limited experience in thyroid disease when the basal metabolic rate was plus 61. A review of the hospital record clearly shows that postoperative hyperthyroid crisis was the immediate cause of

* Case 11 omitted due to the existence of aortic regurgitation

death With adequate pre-operative therapy and skilled operative technic, the operative mortality would have been only one of the 34 treated surgically, a mortality of 2.9 per cent

It is highly significant that two patients died from the effects of acute hyperthyroid crisis before the hyperthyroidism could be controlled with iodine and before surgery was attempted If one eliminates the clearly preventable fatal operative complications, he finds that two patients died without any attempt at surgical relief while only one died following thyroidectomy These facts need emphasis for there are those who, because of their fear of the operative mortality, are inclined to withhold surgical therapy In this group of patients the "medical" mortality was higher than the "surgical," if one eliminates the deaths incident to faulty surgical technic

During the same period of time covered by this study, 71 white patients were treated for hyperthyroidism at Memorial Hospital^{*} without a fatality All of these had a subtotal thyroidectomy preceded by medical preparation similar to that used routinely with the negro patients No case had, either before or after operation, a hyperthyroid crisis This comparison clearly indicates that hyperthyroidism is a more serious problem in the negro than in the white patient, not because of a fundamental difference in the nature or severity of the disease, but rather because of delay in seeking adequate treatment

COMMENTS

The occurrence of hyperthyroidism in an area almost entirely free of endemic goiter is of peculiar significance for it naturally stimulates an inquiry into the causes which operate in bringing about the condition That the factor, or factors, are potent in their effect on the negro is definitely proved by the study, for Graves' disease is proportionately as common in the negro in this area as in the white race

If there is a difference in the reaction of the negro and the white patient to hyperthyroidism, it is probably a quantitative rather than a qualitative one for our impression is that the negro has less ability to adjust himself to the disease This is particularly true of the cardiovascular apparatus, yet, in estimating the effects of increased metabolism on the heart, one must reckon not only with the percentage increase of oxygen requirements, but with the state of the peripheral vascular tonus and energy expenditure due to physical effort There was not the usual lowering of diastolic blood pressure in the negro patients observed in this study, and the occupations of all the patients required more physical effort than that required in a similar group of white patients

While these facts are undoubtedly important in exaggerating the effects of hyperthyroidism on the heart, they do not adequately explain the high percentage of significant alterations found in negro patients

^{*} For white patients only, similar staff at both hospitals

The other most significant differences in the reaction to hyperthyroidism as observed in the negro are the phenomena referable to the nervous system. While the basal metabolism is elevated, restlessness, tremor and the usually observed phenomena of stimulation are characteristically evident and of great severity, yet, relief is prompt and complete as soon as the hyperthyroidism is controlled. The average patient is entirely free of all symptoms within two weeks following subtotal thyroidectomy and we have not observed a single negro patient who required a prolonged period of convalescence for the nervous system to adjust itself. This is undoubtedly an index to the nervous mechanism characteristic of the negro.

In a recent study by one of us³ of bichloride poisoning, it was noted that there had been admitted to the Hospital Division of the Medical College of Virginia 71 patients in whom corrosive poisons had been taken with suicidal intent. There was only one negro patient in the group and she was a mulatto school teacher.

The negro is distinctly an emotional type of individual, but he has few inhibitions, hence, outlets are free and easy with the result that suicide is rare and probably for the same reason the effects of thyroxin trauma quickly disappear following the relief of hyperthyroidism.

To postulate a pathogenetic concept of Graves' disease from this study of the malady in the negro living in a non-endemic goiter area is not possible with the present lack of any common understanding concerning the real nature of the disease.

We do not believe that the "stress of modern civilization" is a factor, for, though the negro's economic stress is great, his philosophy assures complete adaptation, and emotional trauma is rarely deep or lasting in its effect.

The rarity of endemic goiter in this area quite definitely outlaws the idea of an absolute iodine deficiency as an important etiological factor. The more recent observations of Marine⁴⁻¹⁴ strongly indicate that diet can and may be a significant factor in the pathogenesis of the Graves' syndrome. From this study it is not reasonable to suggest what nutritional factors, if any, operated in the production of exophthalmic goiter in the negro living in a geographic area where endemic goiter is rare, yet, the probability of such an etiological factor is intriguing.

In the negro patients seen in the Out-Patient Clinic and hospital wards there are prevalent quite evident nutritional defects which are traceable to a diet high in carbohydrates, not adequately supplied with complete proteins and milk, woefully lacking in vegetables and fruits, and frequently deficient in total calories. Though this be true, it is not possible to assemble even circumstantial evidence incriminating any specific essential food deficiency. In the final solution of the pathogenesis of exophthalmic goiter, it is probable that many factors will be found that operate jointly in precipitating the syndrome. It is certain that iodine deficiency and the trauma of "modern life" are not the sole factors concerned.

CONCLUSIONS

1 Hyperthyroidism is a relatively common malady in the negro living in this geographical area

2 The disease manifests itself clinically as typical Graves' disease and is accompanied by a diffuse hyperplasia of the thyroid gland

3 The cutaneous changes are of peculiar interest and of real diagnostic importance

4 The cardiovascular apparatus of the negro patient suffers greatly from the effects of hyperthyroidism largely because of delay in seeking adequate treatment

5 Some factors other than primary iodine deficiency or the stress of urban life must be found to explain adequately the pathogenesis of exophthalmic goiter This study leaves the question of specific etiology unanswered

THE ACUTE AND SUBACUTE PULMONARY INVOLVEMENT IN RHEUMATIC FEVER WITH NOTES ON THE COMPLICATION OF BASAL PULMONARY COLLAPSE¹

By BENJAMIN A. GOULEY, M D, *Philadelphia, Pennsylvania*

THERE has been in recent years a renewed interest in the pulmonary lesions of rheumatic fever. Rabinowitz¹ (1926), basing his opinion upon clinical data, felt that there was a distinct rheumatic pneumopathy. In conjunction with Eiman, in 1927, we described certain previously unrecorded gross and histologic pulmonary lesions occurring in rheumatic fever,² and we elaborated upon these in 1932.³ We concluded that pulmonary involvement in rheumatic fever was common and the changes specific. In the meantime, other reports appeared in England (Naish, 1928⁴, Fraser,⁵ 1930), based on independent observations and with similar conclusions.

We judge by the references that come to our attention that the view that rheumatic fever involves the lungs and produces characteristic changes is being more and more widely held, though this view is by no means universal. Our own continued study of this subject, both clinical and pathologic, has increased our conviction that such is the case and that involvement of the lung to some degree in rheumatic fever is as common as that of the heart. We further feel that the acute pulmonary changes lead to permanent alterations and that the latter play a very important rôle in the strain and ultimate defeat of the right ventricle, which has heretofore been ascribed to the mechanical influence of mitral stenosis alone. We hope soon to present the evidence for this belief.

If this conception of the influence of the rheumatic pulmonary lesions on the course of rheumatic heart disease be eventually borne out, it is obvious that the rheumatic pneumopathies will take on a very important aspect. With this in mind, we wish to review the clinical picture caused by the acute lesions, to compare it with that of other common lung inflammations, from which it differs considerably, and also to add a brief comment on an interesting complication that develops in the acute and subacute phases, namely, an "inflammatory collapse" of lung tissue. Our concept of the clinical picture of the rheumatic pneumopathy has been formed by study of more than 25 patients, in whom necropsy revealed cardiac and pulmonary lesions. The pathologic changes are similar to those described in previous articles and will not be discussed here.

The degree and extent of pulmonary inflammation vary greatly with a correspondingly wide variation in the clinical picture. It is an interstitial

* Received for publication April 16, 1937.

From the Departments of Pathology and Cardiology of the Philadelphia General Hospital and Laboratory of Pathology, University Medical School.

inflammation, which in severe involvement is accompanied by alveolar exudate giving rise to frank consolidation, the physical signs are then indicative of pneumonia. In the majority of cases, the involvement is moderate to slight, the interstitial pneumonitis being less intense, confined to smaller areas and accompanied by little and patchy alveolar consolidation. In such cases the physical signs are less conspicuous and often the pulmonary lesion is revealed only by necropsy.

Lung involvement usually appears shortly after the onset of polyarthritis, occasionally precedes it, and in many instances, especially in children, it may dominate the clinical picture from the beginning, the arthritic phenomena being slight or indeed entirely absent. In such cases the latter development of pericarditis and endocarditis will reveal the rheumatic nature of the infection. This type of pneumonia does not depend upon the presence of bronchitis after the fashion of ordinary bronchopneumonia but will often follow as do the other types of acute rheumatism, shortly after the development of sinusitis, nasopharyngitis, and tonsillitis, as a part of the widespread systemic reaction to streptococcal infection.⁶ It should not be regarded as a complication of rheumatic fever, rather is it an integral part of that disease, as much so as endocarditis.

The Clinical Picture of Rheumatic Pneumonia and Pneumonitis The pulmonary involvement is usually insidious, there being little in the appearance of many patients that would direct the physician's attention to the possible existence of pneumonia. Examination of the lungs will often reveal not only in children and adolescents, but also not infrequently in adults with acute rheumatic fever, areas of bronchial breathing and dullness on percussion, suggestive of consolidation. The bronchial breathing is sometimes loud, at other times muffled and distant, in some patients expiration lacks the exquisite high pitch heard over the consolidation of pneumococcus lobar pneumonia. So-called acute emphysema will sometimes be present, due to an acute inflammatory turgescence of the lung tissue. These signs are best elicited posteriorly over the lower lobes, they are often conspicuous at the angle of the scapula, and to a lesser degree are found in the axillary areas. The upper lobes are not immune to involvement. Where bronchial breathing is pronounced, egophony and whispered pectoriloquy may be noted. Râles may or may not be present, they are of variable quality, and are seldom heard in the same number and intensity as in pneumococcus lobar pneumonia. There are, however, occasional cases in which the physical signs of consolidation are almost identical with those found in pneumococcus pneumonia. The similarity exists for only a short time because the transient character of the rheumatic lesion is in striking contrast to the orderly and progressive resolution of the pneumococcus consolidation. What on one day appears to be characteristic consolidation with tubular breathing may appear within the next day or two as an atelectasis with very distant tubular breathing or often with an absence of breath sounds. The signs of con-

solidation may appear in another lobe, in some patients the successive involvement and abatement in a number of areas suggest an analogy to the course of the polyarthritis. Consolidation may recur in the same area within a few weeks in virulent cases. In many patients the physical signs of pulmonary involvement, while unmistakable, suggest that the inflammatory reaction has not gone on to true consolidation since typical bronchial

FIG 1 Right lung from a case of rheumatic pneumonitis, subacute stage showing basal collapse. Note marked diminution in size of the lower lobe. There was a small effusion in both pleural sacs and an acute pericarditis with 250 c.c. of exudate. The effect of the latter on the production of a right sided collapse was probably negligible.

breathing is absent—indeed more frequently the breath sounds are distant or obscured by râles. In such cases the term “pneumonitis” will be preferred by many physicians. This milder degree of involvement is probably that which is most commonly encountered.

There is a surprising disproportion in most cases between the symptoms and the physical signs, even when the pulmonary involvement is fairly extensive. A comparison with the clinical course of pneumococcus lobar pneu-

monia will emphasize this point. The classical picture of lobar pneumonia calls for an initial chill, prolonged and high fever, usually severe pleural pain, rusty sputum, marked elevation of the respiratory rate and crisis, these are not observed in rheumatic pneumonia and their absence is largely the reason for the tardy recognition of an important clinical phenomenon. The initial chill that signalizes the onset of pulmonary invasion has not been noted, or at least is not striking enough to achieve distinction from the mild chilliness that recurs from day to day in some rheumatic fever patients. There may

FIG 2 Lobular atelectasis developing in the course of acute interstitial rheumatic pneumonitis ($\times 33$)

or may not be a cough, if present it is rarely troublesome, and never very productive. In some cases, the sputum is blood streaked, which may be ascribed by the attending physician to passive congestion secondary to cardiac failure, though it probably has its origin in the hemorrhagic alveolar exudate of the pneumonia. The sputum does not present any special bacteriological findings. Pneumococci may be found, but not as a predominant organism, streptococci, both of the hemolytic and of the viridans strains, will often be present. Such findings may represent only the bacterial flora

of the nasopharyngeal sinus or tonsillar infection, few organisms, often none at all, are found in the inflamed lung tissue

The absence of respiratory distress in most patients is striking. Expiratory grunt and the play of the nostrils, common in lobar pneumonia, are seldom present. The respiratory rate is slightly or moderately elevated, irregularly so. This is all the more remarkable in view of the fact that a serious myocarditis often coexists. In occasional cases where both lungs

FIG 3 Early congestive phase of acute interstitial pneumonitis showing marked capillary congestion, early interstitial infiltration of endothelial cells and beginning collapse. There was no obstructive change in the bronchial tree ($\times 276$)

are almost entirely consolidated, the respiratory rate will quickly rise in what usually develops to be a terminal phase.

Pleural pain is relatively rare. Most patients never complain of it, but, in contrast, a considerable number have substernal pain due to pericarditis. Fibrinous pleurisy, often observed at necropsy,⁷ has been accorded a degree of importance in the literature which is not altogether warranted by its observable clinical manifestations. While friction rubs are not uncommon, pleural pain, curiously enough, has been encountered only in the minority of patients with pulmonary consolidation. In only two instances in a series of

25 patients was lancinating pleural pain the striking initial feature—as it so commonly is in pneumococcus pneumonia. Empyema as a direct complication has not been present either clinically or in the cases that we have seen at necropsy. Its rarity in rheumatic fever was pointed out many years ago by Longstreth *⁸

The fever is usually moderate, in some instances high, but very irregular

FIG 4 Showing early acute interstitial rheumatic pneumonitis and beginning collapse. Note acute destruction of the elastica, it is preserved in the walls of the small veins (V) but has practically disappeared from the interstitial alveolar structure, a few dark stained shreds and granules remaining (Weigert stain) ($\times 276$)

(102 to 105°), and probably related to the systemic infection rather than to the local pulmonary changes. Our experience does not coincide with that of Naish who was impressed by the minor character of the febrile elevation in most of his cases. It is possible that salicylate therapy may have been partly responsible for this difference, usually the presence of marked pulmonary involvement is associated with a severe type of infection, in which the febrile reaction is considerable. There is no crisis, the fever follows the

* Morris Longstreth, Pathologist (1872-1879) and Visiting Physician to the Pennsylvania Hospital (1879-1895)

irregular course seen in such severe cases, and gradually falls in proportion to the general recovery from the rheumatic disease

In most cases the pulmonary involvement is obscured by the generally severe symptom complex that is known as acute rheumatic fever, and apparently adds little to the already existent toxicity. There is a small group of patients in whom the pulmonary invasion is extremely rapid and widespread, accompanied by quickly developing dyspnea and cyanosis. In such

FIG 5 Showing subchronic interstitial rheumatic pneumonitis complicated by excessive interstitial fibrosis in a collapsed area. It is doubtful whether such lung tissue can ever regain its pre-inflammatory resiliency ($\times 276$)

instances the pulmonary involvement can suddenly alter the prognosis and can be regarded as the actual cause of death

The rheumatic and the pneumococcic pneumonias can co-exist in the same lung, but our necropsy experience suggests that such occurrence is distinctly uncommon. The ordinary type of bronchopneumonia may co-exist or occur as a secondary infection, but this association is also, we think, uncommon. The large majority of rheumatic fever patients with lung involvement do not have a history of preceding bronchitis, nor do they have

the purulent expectoration or diffuse bronchial moisture usually noted in cases of suppurative bronchitis or the common type of bronchopneumonia

Laboratory Data The laboratory data differ in no way from those usually recorded in rheumatic fever, namely, a leukocytosis of 10,000 or more, occasionally mounting as high as 25,000, the differential count usually shows a moderate increase in both neutrophils and monocytes. Blood cultures were done in only a few cases and were always negative.

Roentgen-ray examination of the chest is often disappointing. Areas of moderately increased opacity (mild cloudiness of lung fields) without well defined borders are often interpreted as passive congestion. These patients usually do not have marked congestive heart failure. Where there has been opportunity to repeat the roentgenogram within a few days there has been noted in a few instances, rapid spread and regression of this haziness, corroborating the transient changes noted clinically in the same patients. There is a remarkable example of a complete subsidence within four days pictured in Poynton and Schlesinger's⁹ text "Advances in the Study of Rheumatism" (1931). The attending physician refused to believe that a pneumonia could so completely subside in such short time.

The Subclinical Pulmonary Involvement of Rheumatic Fever It can safely be said that the majority of moderately ill rheumatic fever patients will not show anything like the striking physical signs of consolidation or of widespread pneumonitis. With increasing evidence of the importance of the pulmonary lesions, however, more complete examination should be attempted and fleeting changes will possibly be detected in many milder cases of rheumatic fever. Moderately impaired breath sounds, slightly to moderately impaired percussion note and possibly a few râles will constitute the "subclinical" lung signs, very brief and not very convincing, yet probably of great importance in the subsequent clinical course of cardio-pulmonary dysfunction. These statements are based on the fact that many patients with negative chest findings in the ordinary routine examination present slight to moderate pneumonitis of the characteristic type at necropsy, in fact, the incidence of pneumonitis in some degree is almost the same as that of myocarditis.

"Inflammatory Collapse"—A Complication of Rheumatic Pneumonia and Pneumonitis The physical signs of consolidation may disappear rapidly in the course of a few days and are not infrequently followed by dullness and impaired or absent breath sounds at the bases. These latter signs may have been present from the beginning. At any rate they persist for many days, even weeks, and are due to pulmonary collapse or atelectasis, usually accompanied by small pleural effusions. This collapse has been noted frequently on the left side and is currently attributed to atelectasis secondary to pericardial effusion. Coombs¹⁰ ascribed it to reflex immobilization of the left diaphragm following pericarditis, we have seen it as a right sided lesion in the absence of pericarditis. Naish suggested that the

constant friction caused by the pulsating heart probably dictated the development of primary inflammation in the adjacent left lung but he rejected the older theory of cardiac pressure with subsequent pulmonary collapse. Possibly a number of factors operate, namely the small to moderate pleural effusions that often accompany the atelectasis, the prolonged confinement to bed with its subsequent diminution of pulmonary function, and probably in some instances, a reflex inhibition of diaphragmatic activity as postulated by Coombs. However, these possible factors do not afford a sufficiently reasonable explanation in the majority of cases. The pleural effusions are usually too small and sometimes absent, as shown at necropsy, and certainly are not to be compared with the massive hydrothorax of chronic congestive heart failure where the atelectasis is less striking in extent.

The most important factor we believe is the pneumonia or pneumonitis *per se*. Basal collapse can be seen not infrequently in conditions other than rheumatic fever, for example, in senile emphysema in conjunction with pleural effusion. (We exclude from consideration the ordinary types of atelectasis—the bronchial obstructive and the compressive.) Evidently the resiliency of the lung tissue is a factor in the development of basal collapse. Following rheumatic pneumonia, there is a distinct loss of the normal elasticity of the parenchyma, a direct result of the “fibrinoid” degeneration of the alveolar walls, with the destruction of the elastic and reticular fibers of the interstitial framework. There is finally a replacement by an interstitial fibrosis in which there is usually a marked regenerative hyperplasia of coarse, irregular and fragmented elastic fibers, the net result of which is not a return to the normal elastic state but a lung tissue that is much firmer, with rubberoid consistency. Where the loss of the elastica has been great and respiratory function temporarily destroyed, the inflammatory congestion marked and air-absorption facilitated, collapse fibrosis is apt to occur. Since the incidence of rheumatic pneumonitis is greatest in the lower lobes, they are the favored site for the development of this lesion. Moreover, those factors which we believe to be of secondary importance, namely, pleural effusion and pericardial effusion will exert their influence largely on the lower lobes. Collapse may involve an entire lobe or a portion of it, and it follows from the foregoing statements that such gross involvement is almost always basal, the collapse, however, may be of lesser proportions, giving rise to small lobular atelectases, we have noted instances of lobular atelectasis in the upper lobes, a location practically immune to the influence of pleural effusion.

The lesion may be termed “inflammatory collapse” in contra-distinction to the mechanical types produced by either external compression or bronchial obstruction. The physical signs of basal dullness and impaired breath sounds often noted even late in convalescence from a severe attack of rheumatic fever, are typical of this lesion. Coarse râles differing from those heard earlier in the state of intra-alveolar consolidation also may persist for

many days or weeks and can be ascribed to a plastic pleural reaction. Whether consolidation necessarily preceded this state or whether severe grades of pneumonitis, short of actual consolidation may equally lead to this same result, cannot be stated with any certainty. Roentgenograms may reveal elevation of the diaphragm on one or both sides, with or without small pleural effusions. "Hypoventilation" of the lungs due to elevation of the diaphragm is a diagnosis occasionally made by the roentgenologist.

It is questionable whether the function of such collapsed lung tissue can ever return to normal. In a case recently seen at necropsy, the lower right lobe was still considerably shrunk in size two months after the diagnosis of rheumatic pneumonitis had been made. We have no later direct observations on this point, but inasmuch as the interstitial fibrosis that follows rheumatic pneumonitis will in all likelihood be exaggerated in areas that were collapsed, it is reasonable to assume that respiratory function will remain impaired in spite of re-aeration. It is believed that respiratory exchange is diminished in areas of interstitial pulmonary fibrosis (the state known in the German literature as "pneumonose")^{11, 12, 13}

*The Probable Relationship of Ewart's Sign (of Pericardial Effusion)*¹⁴ to Rheumatic Pneumonia and Inflammatory Collapse.* Bronchial breathing suggestive of consolidation is not infrequently found at the angle of the left scapula, due it is claimed to an atelectasis secondary to pericardial effusion rather than to pneumonia. This is an old observation known as Ewart's sign. It is significant that while this sign is encountered in the great majority of instances in young patients with rheumatic fever, much greater effusions noted occasionally with tuberculous pericarditis do not produce identical signs of "false" consolidation.

We have had ample opportunity to study sections from atelectatic left lungs in acute rheumatic fever with pericarditis. Such sections show a pneumonitis, a definite inflammatory reaction similar to the pneumonia or pneumonitis encountered in the right lobe, of the same patient if such a localization has developed, or in the right lung of other patients. The tendency to collapse in rheumatic pneumonitis, described in earlier paragraphs as due to the impaired elasticity and destruction of normal interstitial connective tissue, is the probable basis of Ewart's sign. Lung tissue so involved is probably vulnerable to pressure from any direction, if this assumption is correct, then pressure exerted by pericardial effusion merely hastens and accentuates the signs of a pulmonary inflammation already present.

SUMMARY

Pulmonary consolidation constituting a true pneumonia is often seen in severe cases of rheumatic fever, a lesser degree of lung involvement, not

* Ewart listed ten signs of pericardial effusion, of which the eighth dealt with "the posterior pericardial patch of dullness," a sign previously noted by Bamberger (1867), Pins (1889), and Samson (1892), the tenth was the "posterior pericardial patch of tubular breathing and egophony" which has been combined by usage with the eighth sign as Ewart's sign of pericardial effusion.

actual consolidation, preferably termed "pneumonitis," is frequently encountered. These changes are not secondary complications but an integral part of the disease. The clinical manifestations are often overlooked because of the transient character of the consolidations and the inability to examine the bases of the lungs of patients wracked with arthritic pain.

In most patients with rheumatic pneumonia there is a characteristic disproportion between symptoms and physical signs, the latter being the most striking. Respiratory distress is comparatively slight but becomes marked when pulmonary involvement is almost complete. The acute inflammation is followed in some cases by a characteristic "inflammatory collapse," usually basal, the main factors appear to be a loss of elasticity, air-absorption, and subsequent contracture due to interstitial pneumonitis.

THE NECESSITY OF CERTAIN CRITERIA FOR THE DIAGNOSIS AND CURE OF RHEUMATOID ARTHRITIS*

By RUSSELL L. CECIL, M.D., F.A.C.P., *New York, N. Y.*

PERHAPS the most important problem which confronts a young medical organization such as the American Rheumatism Association is the proper orientation of the Society in the field which it proposes to cover. This question has already been attacked in part by this group. In the first place we decided that we would not confine ourselves strictly to the matter of arthritis, but would cover the whole field of rheumatism, including rheumatic fever. Our next task is to attack the problem of nomenclature, and what a difficult problem it is! The English have already made a brave effort in this direction, and their achievements are covered in the report of the Subcommittee on Nomenclature of the National Rheumatism Committee, which was appointed by the Royal College of Physicians. In our own country the American Heart Society has set us a fine example in their classification and nomenclature of diseases of the heart. This subject is much too large to be covered by a president's address. Today I simply wish to point out the necessity of establishing certain criteria for the identification of rheumatoid arthritis, a disease which might well be called the key-stone of our problem. I shall also say something concerning the criteria essential for the pronouncement of cure in this disease.

Rheumatoid arthritis is one of the great diseases of medicine. With tuberculosis and syphilis it constitutes the great triad of chronic granulomatous infections prevalent in our climate. This fact in itself would help to explain the rapidly growing interest in chronic arthritis, and in rheumatoid arthritis in particular. But there is an even stronger reason for the increasing interest in rheumatoid arthritis. It is one of the few remaining unsolved problems in the field of infectious diseases. To be sure, there are many things we do not understand about tuberculosis, syphilis, pneumonia, and other infectious diseases, but at least we know their causes. In the case of rheumatoid arthritis we are still debating the etiology, and much work remains to be done before this problem can be settled. Etiology, however, is only one of the many problems connected with rheumatoid arthritis. We must learn more about the influence of heredity and other predisposing factors such as climate, constitution, malnutrition, avitaminosis, etc. And finally, we must learn how to treat the disease successfully. We might say that rheumatoid arthritis today stands in the same position that tuberculosis occupied 60 or 70 years ago before Robert Koch discovered the tubercle bacillus. Rheumatoid arthritis is waiting for its Robert Koch, and I for

* President's Address, read before the Fourth Annual Meeting of the American Rheumatism Association at Atlantic City, New Jersey, June 7, 1937. Received for publication July 9, 1937.

one believe that within the next 10 years he will probably make his appearance

Before taking up in detail the criteria which are necessary for the diagnosis of rheumatoid arthritis, let us review briefly the classification of the British National Committee¹ Under the heading of "rheumatoid arthritis" we find the following subdivisions

(1) Rheumatoid arthritis with associated factors Under this heading are placed metastatic or focal arthritis, including so-called multiple infectious arthritis, in other words, the rheumatoid type of arthritis closely associated clinically with focal infection Under the same heading the English classifiers place rheumatoid arthritis associated with the disordered metabolism of the menopause—a rather dubious effort to tie up the disease with another well recognized pathologic condition

(2) Rheumatoid arthritis with no known associated factors Under this heading the British include the classic type of rheumatoid arthritis as it is seen in women during the child-bearing period I might add that it is also seen at this time of life in men even though they do not bear children Under this heading the British also include Still's disease, or the rheumatoid arthritis of children The British Committee then draw a "deadly parallel" between rheumatoid arthritis with known associated factors and rheumatoid arthritis with no known associated factors, and attempt to make a clinical distinction between the two groups The differentiation occupies more than four pages of text, the reading of which does not convince one that such a differentiation is feasible or desirable About the only real difference between the two groups is that the first group is associated with definite focal infection whereas in the second group no focus of infection is demonstrable, but we all know how frequently foci of infection can be missed, even after the most careful study, and we also know that on the other hand teeth, tonsils, and sinuses are often blamed for crimes which they did not commit Therefore, it seems to me that this differentiation of rheumatoid arthritis into two groups, while intriguing, is not justified So far as we have been able to make out from our studies, both types present the same pathological and clinical manifestations, and the immune responses are the same for both groups For the time being, therefore, I suggest that in America we continue to look upon rheumatoid arthritis as a single disease and that we attempt to establish certain criteria for its identification

In discussing the necessary criteria for the diagnosis of rheumatoid arthritis, we may divide them into pathological, clinical, radiological, and serological findings

1 The pathological criteria are quite definite, but unfortunately are not obtainable except by means of a biopsy In a certain number of cases a synovectomy may be indicated and tissue becomes available for microscopic study The gross pathology of the joint is not sufficiently characteristic¹⁴ might be simulated by some other form of joint infection, particularly the

gonococcal joint Microscopically, a vascular granulation tissue containing collections of lymphoid cells which often resemble true lymphoid follicles, presents a picture which in my experience, one never sees except in rheumatoid arthritis If a subcutaneous nodule presents itself it can readily be removed, and again microscopic study reveals the characteristic histologic changes so well described by numerous pathologists As pointed out by Dawson,² these changes do not differ widely from those observed in the subcutaneous nodules of rheumatic fever However, the nodules of rheumatoid arthritis are usually larger than those of rheumatic fever, and not so likely to appear and disappear

2 Clinical Criteria The clinical criteria of rheumatoid arthritis are perhaps the most important of all, and of these, the most characteristic is the fusiform finger Periarticular swelling is of course a feature of any form of joint infection, but the peculiar, doughy enlargement of the proximal interphalangeal joints of the fingers is the outstanding badge of rheumatoid arthritis The fusiform finger usually appears early in the disease and may persist for years Eventually however, as the disease passes into the inactive stage, the swelling in large part disappears and is replaced by ankylosis and deformity Closely associated with the fusiform swelling of the fingers, and almost as frequent is a swelling of several knuckles, which when accompanied by atrophy of the interosseal muscles, gives the hand its characteristic appearance

The second clinical criterion is the multiplicity of joints involved The disease is still often spoken of as chronic multiple arthritis It is indeed rare to see only one joint affected I recall in my practice one young woman who showed a fusiform swelling of the index finger of the left hand She was a slender under-nourished girl of 23 years, and I fully expected to see the disease extend eventually to other joints However, no other joints were ever involved during the two years or more that she was under my observation During that time the swelling of the finger remained practically unchanged I was suspicious of tuberculosis in this case, but it could not be proved by roentgen-ray or other diagnostic methods In discussing the characteristic lesions of the hands and fingers in this disease, I am tempted to include the frequent involvement of the wrists and particularly their early tendency to ankylosis However, this could hardly be looked upon as one of the essential criteria, neither could the vasomotor disturbances of the hands and feet, though I always expect the rheumatoid arthritic to greet me with the cold, clammy hand so typical of the disease The wasting of the muscles and the atrophy of the skin and subcutaneous tissues are seen in other forms of infectious arthritis as well as in the rheumatoid type There are other favorite sites of rheumatoid manifestation, particularly the knees, feet elbows and cervical spine I have never been able to understand why the hips and the toes so frequently escape involvement

I have already referred to the highly characteristic subcutaneous nodule. When present, it is almost pathognomonic of the disease, but unfortunately it occurs in only 4 or 5 per cent of cases. Certain other clinical phenomena, such as iritis, psoriasis and the various forms of erythema, are frequently associated with rheumatoid arthritis, but could in no sense be considered as criteria of the disease.

Should the physician ever make a diagnosis of rheumatoid arthritis in the entire absence of swelling or deformity of the joints? Only rarely would such a diagnosis be justified, though one might be strongly suspicious of what I often call the pre-arthritic stage of the disease.

3 Radiographic Criteria The roentgen-ray appearance of the bones and joints in rheumatoid arthritis is highly characteristic, so much so that it is usually possible to make a diagnosis of the disease by this means alone. In the very early stages there are no typical manifestations. Soon, however, the roentgen-rays begin to show the characteristic decalcification of the bones and the soft tissue swelling. As the disease progresses there is narrowing of the inter-articular space due to thinning of the cartilage, and blurring of the whole joint architecture. Several writers have stressed the peculiar punched-out areas, which are a prominent feature of rheumatoid arthritis, and occur just as frequently in this disease as in gout. In the latter disease, however, the punched-out areas are much larger than those in rheumatoid arthritis. In the final stages of rheumatoid arthritis the joint surfaces may become fused through fibrous or bony ankylosis, and in deformed joints there may be subluxation or dislocation. In the late stages hypertrophic changes may be observed, but this should not lead to confusion of the disease with osteo-arthritis.

Can a definite diagnosis of rheumatoid arthritis be made from the roentgen-ray pictures alone? In very early cases, no. In well established cases, yes, in a high percentage of cases. Occasionally, a gonococcal arthritis might be a source of error, but the anamnesia and other clinical data would prevent a mistake in diagnosis.

4 Serological Criteria The most characteristic blood change in rheumatoid arthritis is the agglutination of the *Streptococcus hemolyticus* by the patient's serum, usually in high dilutions. This test is positive in a large proportion of cases, the actual percentage of positive reactions depending on the duration of the disease. In early cases the presence of agglutinins is not so conspicuous a finding, but in the original report which the writer made with Nicholls and Stainsby in 1931,³ we obtained a positive agglutination reaction in 97 per cent of 153 cases of well established rheumatoid arthritis. Dawson, Olmstead and Boots⁴ demonstrated the presence of streptococcal agglutinins in 67 per cent of their series, Blair and Hallman,⁵ in 85 per cent of their patients.

We may conclude then that while a positive streptococcal agglutination reaction is present in a high percentage of cases of rheumatoid arthritis, it

is not invariably present. It may be said, however, that a positive agglutination reaction is strongly confirmatory of rheumatoid arthritis and should be looked upon as one of the important diagnostic criteria.

Other immunological phenomena have been noted in the serums of patients with rheumatoid arthritis. I refer to the ability of rheumatoid sera to precipitate the various group specific fractions of the *Streptococcus hemolyticus* and to the presence of anti-streptolysin in the sera of some patients with this disease. Neither of these antibodies, however, is so consistently present as are the agglutinins. For this reason they could not be looked upon as important criteria in the diagnosis of the disease.

Another reaction of considerable importance is the sedimentation rate of the red blood cells. The sedimentation rate shows sharp acceleration in practically 100 per cent of cases of rheumatoid arthritis during the active stage of the disease. This test of course does not differentiate rheumatoid arthritis from other forms of infectious arthritis. However, a rapid sedimentation rate is an important feature of the disease.

A moderate grade of leukocytosis, with some increase in the percentage of immature cells, is seen in a good many cases, but is not a constant enough finding to be dependable. The same is true of the secondary anemia which so frequently accompanies the disease.

Summarizing then, we may say that a patient with rheumatoid arthritis should present the picture of a chronic progressive multiple arthritis characterized in its earlier phases by soft tissue swelling, and in its later stages by some ankylosis and deformity. Implication of the interphalangeal, metacarpophalangeal and wrist joints is especially characteristic. The synovial membrane and the subcutaneous nodules, when present, show specific histological changes. The radiographic evidence is quite typical, and the patient's serum in a large majority of cases will induce an agglutination of the *streptococcus hemolyticus*. A rapid sedimentation rate of the red blood cells is highly characteristic, but is seen in other forms of infectious arthritis as well.

Let us now turn our attention for a few moments to the question of criteria for determining the cure of rheumatoid arthritis. Such criteria are obviously needed and should serve as a guide to any of our members who report on the effects of this or that remedy in the treatment of the disease. There are entirely too many articles being written on the treatment of rheumatoid arthritis. Most of them fail to take into account the natural tendency of the disease to remissions and exacerbations, and the writers are too content to state that such and such a percentage of patients were "improved" by the treatment under consideration. Personally I will not be permanently satisfied with any remedy for arthritis which merely improves the patient. We must strive for a *cure*, something that will give the patient complete and permanent relief from the disease. When should we be willing to pronounce the rheumatoid patient cured? I should say that the first

requirement would be clinical cure evidenced by freedom from pain and swelling of the joints and partial or complete return of joint function. In addition to freedom from joint symptoms the patient should feel well and should be entirely relieved of the exhaustion and fatigability which so frequently accompany the disease. At this point, however, we must make certain qualifications in our criteria. It is true that cure in an early case frees the patient from practically all earmarks of the disease. In those comparatively rare instances, however, where a well-established arthritic recovers from the disease a number of scars may remain. The patient returns to normal health and the joints are free of swelling and pain, but there may be some residual enlargement. Ankylosis and deformity may persist in certain joints, but the patient does not mind this when he feels so well in all other respects.

In a cured case the sedimentation rate of the red cells should return to normal, and the specific agglutinins for the hemolytic streptococcus should disappear from the patient's serum. The leukocyte count returns to normal, and the secondary anemia is replaced by a normal blood count.

Roentgen-ray pictures may reveal certain residual damage to several of the joints, but in early cases radiographs may show little or no evidence of permanent joint damage.

The patient should not be looked upon as a cure until he has remained free of symptoms for at least one to two years.

Would it not be worth while for this Society to appoint a committee whose duty it could be to set up certain criteria for the diagnosis and cure of rheumatoid arthritis? The acceptance of such criteria by the members of this group would, in my opinion, greatly advance the cause of efficient therapy. When the curative effects of the numerous types of therapy were analyzed with such criteria in mind, perhaps fewer but more intelligible contributions to the literature of rheumatism treatment would be made.

METABOLIC STUDIES IN A MAN WHO LIVED FOR YEARS ON A MINIMUM PROTEIN DIET *

By FR STRIECK, Ph D , M D , *Wurzburg, Germany*

I have on several occasions had the opportunity of cooperating in making interesting studies of persons who voluntarily carried out with great care and devotion a one-sided extreme diet. Such were the final studies by Dr E F DuBois,¹ upon Dr V Stefansson and K Andersen, both of whom had lived for a long time exclusively upon meat and fat and the internal organs of butchered animals. We were able also in 1933 and later to carry out observations on a well known nutritional physiologist, Dr C Rose, who for 15 years investigated the question of the minimum protein requirement, the protein optimum, the biological value of single varieties of protein and other related problems.

In the study of problems of nutrition, protein, the most important and indispensable of foodstuffs, has been the repeated object of investigation. The literature concerning this substance is almost too great for review, and many questions here seem to be still unexplained. It would be far beyond the limits of this paper to present even a partially comprehensive survey of this problem. The collected literature may be found in the papers of Heupke,² Hindhede, and Susskind.³ I should like to limit myself to a few questions which I have studied in association with Dr C Rose in the last few years, namely, the question of efficiency on a protein poor diet, the total metabolism at the borderline of minimum protein requirement, and the specific dynamic protein effect after feeding varieties of protein of different biological value in varying amounts.

Since there is a want of clearness in the literature concerning the minimum protein requirement, I should like first to briefly define protein minimum. We understand by the minimal nitrogen excretion, which was termed by Rubner the wear and tear quota, the smallest or lowest nitrogen excretion values in an individual on a protein free diet. The physiological protein minimum is found when the minimal nitrogen balance is reached, i e , when output and intake balance one another. The physiological protein minimum is independent of the kind of protein, the state of nutrition or other factors. It is necessary in the technic of the investigation, not only that an analysis be made of the excretions (feces and urine) and of the perspiration and secretions of the skin, but also that there be an exact determination of the composition of the diet which is fed. Differences from table values by as much as 50 per cent may occur. Months or years of prolonged series of

* Received for publication June 23, 1937

From the Medical Clinic of the University of Wurzburg, Prof E Grafe, Director

diets with similar foodstuffs presuppose, if the conclusions are to be clear and unequivocal, a continuous analysis of the single basic foods, such as potatoes, milk, bread, etc. We have carried out these analyses.

Factors which influence the minimal nitrogen excretion are, aside from those already mentioned, the compatibility of the usually very onesidedly constructed diet, vitamins, the amount of fluid, the state of nutrition, the time of life, the acid base balance, and the biological value (quantivalence) of the single varieties of protein.

The very question of the acid base economy is still a much debated question, in connection with which Rose, R. Berg and others have developed a special point of view. The richness in base of the diet and the previous output of acid are of decisive importance in the question of the minimal protein requirement. In careful metabolic studies Rose has recently tested again the relation between minimum protein requirement and the base content of human food. In a preliminary period, with a protein intake of 28.17 gm daily and the addition of basic salt, he found a nitrogen storage of 0.60 gm. The urine was alkaline at this time. In the main period he left out the basic salt, keeping the amount of protein the same, with an exactly similar diet. The urine became acid and the loss of nitrogen amounted to 0.44 gm. If he then added basic substances, a storage of 0.155 gm of nitrogen occurred during the after period. The total calories were 2651 in 24 hours. Rose attributes the negative nitrogen balance on the same nitrogen intake during the main period to the lack of an excess of base. The less the formation of ammonia, the smaller is the wear and tear quota. Thomas had already found earlier that the value for the smallest protein requirement cannot be kept constant with bread and meat, if sufficient basic substances are not simultaneously present. This phenomenon is due to the marked formation of ammonia.

It has already been mentioned that the biological value of individual protein substances differs, that is, the capacity of individual protein substances to attain a minimal nitrogen balance, differs. With milk, Rose achieved this with 20.5 gm protein, in the case of a potato diet, with 26.5 gm, with an exclusive banana diet it required 46 gm.

So far as I know, there have never been any studies anywhere which were carried out on a human being who existed for 15 years on an average daily protein intake of 38 to 40 gm, who during an experimental period lasting for years took daily only 26 gm, and who at times, during periods of negative balance, took only 20 gm of protein. Neither Hindhede nor Chittenden, Thomas, Rubner, or Lusk has been able to carry through such series of investigations. The unique character of these experimental conditions led us to report the results of efficiency tests in this subject.

Rose carried out extraordinary performance tests in 1931 together with his friend Dr. Schmitt, a Swiss physician of Thun, who for 25 months likewise ate only about 30 to 40 gm of vegetable protein with an adequate

caloric intake Dr Rose (D R), at that time almost 70 years of age, climbed several mountains over 4000 meters in height Dr Schmitt (D Sch), who at that time was 35 years of age, climbed in 22 ascents, for example, Monte Rosa (4500 m), the Matterhorn (4500 m), the Weiss-horn, Grosse Viescherhorn and other mountains without disturbance in his efficiency, signs of great fatigue or any indication of exhaustion in spite of the small intake of protein

Because of its general biological significance, I should like to mention in addition the negative balance experiments which Dr Rose carried out on himself We studied him at the end of this period The total protein intake was 23 gm , the minimum requirement as determined from the preliminary studies of years, 28 gm There was no vitamin lack The amount of calories ingested was adequate There slowly developed an increasing loss of appetite, diminution of interest in work and a feeling of depression The experiment had to be interrupted because of these complaints A second period of equal duration had to be interrupted because the complaints grew intolerable

The question as to whether during a state of minimal nitrogen equilibrium, the most strenuous bodily exertion results in a greater output of nitrogen, i e , an increased destruction of protein, in a healthy individual, can be answered in the negative as a result of Rose's studies in Switzerland in connection with his mountain climbing, and our own experiments with the brake ergometer and marching exercises (Marschleistungen) During mountain climbing Rose had a positive balance with 24 to 29 gm protein in his diet and excellent physical efficiency In our clinic D R showed an average nitrogen output of 3.9 gm daily He remained in nitrogen balance For days at a time he worked at the brake ergometer to the point of exhaustion, without developing a negative balance Further he walked 50 km on a hot sunny afternoon in mountainous country without being exhausted or showing an increased nitrogen secretion

It seemed of interest to us to test the oxygen consumption during and after work We made the investigation with Krogh's brake ergometer, changing the load and the speed The same tests were carried out on D Sch by Brumann We were able thus to determine that the oxygen consumption is less per unit of time, but that the period of recovery (corresponding to the oxygen debt) is nevertheless distinctly prolonged We have made approximately 20 similar tests in the past three years, always with similar results

In 1933 and 1935 we studied the basal metabolism after a protein poor period and after meat All the following studies of the respiratory gas exchange were made with the Grafe Universal respiratory apparatus, the gas analyses being carried out with the Haldane Carpenter apparatus

The values are presented in table 1 The amount of rise was calculated in accordance with the Harris-Benedict tables The average elevation both

TABLE I
Basal Metabolism Figures

| Date | Calories | R Q | % |
|---------|----------|------|------|
| 3/13/33 | 1633 | 0.81 | + 16 |
| 3/15/33 | 1636 | 0.82 | + 17 |
| 1/3/35 | 1567 | 0.84 | + 18 |
| 1/4/35 | 1478 | 0.82 | + 11 |
| 1/6/35 | 1489 | 0.86 | + 12 |
| 1/8/35 | 1549 | 0.83 | + 16 |

in 1933 and 1935 is about 15 per cent. The values are not comparable with standard figures since D. R. is an unusually energetic, muscular, high spirited man who, from the biological viewpoint, is not as old as would be assumed from his actual age. On each occasion we gave D. R. a careful physical examination. The findings, including roentgen studies, showed no indication of any demonstrable disturbance or wear and tear in his internal organs. There was complete lack of any definite indication of arteriosclerosis. While in the case of D. Sch. the basal metabolism was depressed by about 10 to 15 per cent during the protein poor period of his test, I found a measurable increase in the case of D. R. I prefer not to consider this a true increase in the total combustion but, for the reasons mentioned above, believe these values to represent his normal figures.

The studies of specific dynamic action which, so far as I am aware, have never previously been carried out on a man of this age under similar nutritional conditions, gave peculiar results in 1933. We were interested in the question of the specific dynamic effect of the protein poor diet. The result surprised us in that the increase in total combustion was extraordinarily high and still remained considerably elevated even after six hours. This was confirmed in a control test.

TABLE II
Specific Dynamic Effect after Potatoes (3/14/33)

| Time | Calories | R Q | % | |
|---------|----------|------|-----|--|
| 1 hour | 2204 | 0.79 | +35 | 350 gm potatoes, 100 gm butter, 20 gm sugar. Total calories 1226.3, P 8.5 gm, F 85.8 gm, C 93.56 gm |
| 2 hours | 1958 | 0.83 | +19 | |
| 3 hours | 2045 | 0.88 | +25 | |
| 4 hours | 1810 | 0.81 | +11 | |
| 5 hours | 2575 | 0.89 | +58 | |
| 6 hours | 2570 | 0.89 | +57 | |

The elevation of metabolism was already perceptible after one hour, and after six hours was still 57 per cent. A few days later we then gave a 10-fold greater quantity of protein in the form of meat (table 3). The maximal increase occurred in the first hour and amounted to 22 per cent.

TABLE III
Specific Dynamic Effect after Meat (3/17/33)

| Time | Calories | R Q | % | 400 gm meat, 73 gm butter Total calories 1194, P 80.5 gm |
|---------|----------|------|-----|---|
| 1 hour | 1986 | 0.83 | +22 | |
| 2 hours | 1866 | 0.87 | +14 | |
| 3 hours | 1839 | 0.71 | +13 | |
| 4 hours | 1940 | 0.72 | +19 | |
| 5 hours | 1809 | 0.81 | +11 | |
| 6 hours | 1955 | 0.82 | +20 | |

After a further three day meat diet we determined the specific dynamic effect again and found a very delayed rise, which began only after four hours. The highest value was attained after $5\frac{1}{2}$ hours amounting to +26 per cent (table 4)

TABLE IV
Specific Dynamic Effect after Meat (3/20/33)

| | | |
|----------------------|--------|---|
| Immediate | - 0.9% | 400 gm meat, 73 gm butter Total calories 1194, Protein 80.5 gm |
| $\frac{1}{2}$ hour | - 1.3% | |
| 1 hour | + 0.2% | |
| $1\frac{1}{2}$ hours | - 1.3% | |
| 2 hours | + 9.0% | |
| $2\frac{1}{2}$ hours | + 3.5% | |
| 3 hours | + 6.7% | |
| $3\frac{1}{2}$ hours | + 2.3% | |
| 4 hours | +16.5% | |
| $4\frac{1}{2}$ hours | +11.1% | |
| $5\frac{1}{2}$ hours | +26.1% | |
| 6 hours | + 9.4% | |
| $6\frac{1}{2}$ hours | +17.3% | |
| 7 hours | +21.7% | |
| $7\frac{1}{2}$ hours | +17.5% | |
| 8 hours | +19.3% | |
| $8\frac{1}{2}$ hours | + 6.7% | |
| 9 hours | + 7.0% | |
| $9\frac{1}{2}$ hours | +10.4% | |

After two years of a protein poor diet, conditions were somewhat different. We arranged, instead of a test of short duration, a period of study lasting 24 hours. The apparatus made it possible to study an individual all day and all night and permitted taking food during the same period. On this occasion the total metabolism rose during the afternoon by 37 per cent. It is to be noted that a small percentage of the increase must be attributed to muscular exertion, as D. R. did not lie quietly at rest. During the night the metabolism fell 13 per cent (table 5). After six days we again studied the specific dynamic effect after meat. The increase here was again about the same as before (table 6). To what may now be attributed the altered behavior of the metabolism?

TABLE V
24 Hour Test (1/5/35)

| Time | Calories | R Q | % | Diet |
|----------------------|----------|------|-----|---|
| 8 15 a m -12 43 p m | 1838 | 0 81 | +24 | 8 15 a m coffee 400 gm , cream 20 gm , sugar 20 gm |

No assured interpretation can be given, as long as the nature of specific dynamic action itself is not clear For the present we must limit ourselves to reporting the observed facts

During the course of the protein minimum experiment we studied the loss of nitrogen through the skin We determined the amount of protein given off by means of the skin and perspiration over an experimental period of five days during which unmeasurable losses were avoided so far as possible The method was the same as that used by Rubner I give our results, inasmuch as these experiments have only rarely been carried out and since in accurate equilibrium experiments these values must be taken into consideration During the five day experimental period there were excreted through the skin 0 483 gm of nitrogen We studied the blood chemistry in the case of D R during the 1935 experimental period both before and after the meat diet The blood sugar was 89 mg per cent before the meat diet, and 92 mg per cent after it was begun The non-protein nitrogen was normal, 39 mg per cent, blood chlorides were 514 mg per cent, blood uric acid 3 32 mg per cent Similar values were obtained during both meat and vegetable diets

From the studies on D R it may be concluded that it is possible to live for years on a one-sided diet which includes protein foods of high biologic value such as potatoes and milk, which has an adequate vitamin and caloric

content, and an amount of protein which is extraordinarily small as compared to the general average consumption and by Voit's and Rubner's figures. In spite of this, vigorous physical activity was possible without any demonstrable hurt and without a negative balance during the period of exertion. D. R. puts great faith in potatoes to cover his protein requirement. He has succeeded in cultivating a potato which is unusually rich in protein and palatable, the protein content of which amounts to more than 2 to 3 per cent. It is no doubt possible to live for a long period, without injury to health, on a low protein diet containing approximately 30 gm of protein. The positive balance is immediately changed to a negative balance if the physiological discharge of vital functions is disturbed by illness. A harmless illness occasions an increased protein consumption under these dietary conditions, thereby bringing about a negative balance. D. R. has often confirmed this. Therefore, a surplus of at least 10 to 15 gm is necessary for the safety of the organism. But other observations also give rise to the presumption that demands are laid upon the vital reserves by such a nutritional program. Towards the end of the two year series of experiments D. Sch. observed that he experienced an increased need of rest, his pulse became slower and the axillary temperature rose. Susskind's investigations cannot be subjected to critical study since they were carried out with a protein which was not biologically of high quality, with insufficient vitamin feeding and without accurate analyses. It may be assumed that he lived for a long time in a state of negative balance and that the marked disturbances and resultant collapse are thus to be explained.

If we compare the experiments of Stefansson and Andersen with those of Rose, representing two extremes, we realize how adaptable the human organism is and how multifarious must be its system of safeguards. The meat and fat eaters showed a normal behavior in every respect—total metabolism, protein metabolism, kidney function, efficiency, blood synthesis—in short, all measureable functions except the calcium metabolism were undisturbed. In the case of Rose too all body functions were normal. Physical efficiency was indeed astonishingly good.

Both forms of diet are out of the question so far as actual practical use is concerned. Strong will power and a high degree of fanaticism are necessary in order to follow so one-sided a diet for a long period of time. That it is possible is shown by these investigations.

SUMMARY

Metabolism studies were carried out on a 70 year old, healthy man who for years had been on a diet containing about 30 gm of protein daily. The basal metabolism was elevated 15 per cent in comparison with the Harris-Benedict figures. The specific dynamic effect of protein was higher after vegetable protein than after meat protein. The blood chemistry was un-

changed Physical efficiency was excellent After the most severe bodily labor there was no increased excretion of nitrogen The nitrogen output through the skin amounted to 0.483 gm over a five day period

A PHARMACOLOGIC STUDY OF THE MECHANISM OF GOUT*

By G P GRABFIELD, F A C P , *Boston, Massachusetts*

DR PRATT'S long interest in and contributions to the subject of gout make it a particularly appropriate subject for his birthday volume. It is especially fitting that these observations be reported here since they had their inception in a research the author was privileged to share with Dr Pratt¹

In these experiments we concluded that the action of cinchophen on uric acid excretion was exerted through the central nervous system. At that time methods for testing this suggestion were wanting. With the development of new methods it became possible to test this hypothesis in the experimental animal. In the last three years I have shown that the above concept is correct and that the effects of cinchophen on uric acid excretion do, in fact, depend upon an intact renal nerve supply. This lends support to the idea that the syndrome of gout is associated with changes in the function of the autonomic nervous system, through a mechanism similar to the one concerned in the action of cinchophen on the uric acid excretion.

Thannhauser² has long maintained that the mechanism of uric acid retention was primarily a renal dysfunction, probably concerned with the nervous connections of the kidney. While the frequent association of nephropathy with gout has been adequately stressed, the numbers of patients without evidence of renal lesions have militated against the whole-hearted acceptance of the renal theory³. Thannhauser based his idea of the effects of the renal nervous mechanism on the experiments of Ellinger and Hirt⁴. These experiments, however, showed relatively small differences and were acute experiments with all the difficulties and extraneous factors that acute experiments under anesthesia entail. Although the variations in excretion that they report seem very small, they evidently felt them to be sufficiently constant and consistent to draw the conclusion that the renal nerve supply affected renal cellular activity and that these nerves, therefore, were "secretory nerves" in addition to being "vasomotor nerves". Marshall and Kolls⁵ working with anesthetized dogs were unable to confirm their results and concluded that these nerves had only a vasomotor function.

In 1931, Pratt and I¹ concluded that the action of cinchophen on uric acid excretion was through the central nervous system. This conclusion was arrived at by a study of the uric acid excretion of normal human individuals and a consideration of the literature. Since that time studies on

* Received for publication August 5, 1937

From the Medical Clinic of the Peter Bent Brigham Hospital and the Department of Pharmacology of the Harvard Medical School

the action of cinchophen have concerned themselves primarily with the toxic effect on the liver and have not thrown any new light on the mechanism of its action on the uric acid excretion. Since the end product of nucleic acid metabolism in the dog is chiefly allantoin with only small amounts of uric acid, it was only with the introduction of a rapid, accurate colorimetric method for the determination of allantoin⁶ that it became possible to undertake a series of crucial experiments as to whether the above-mentioned hypothesis concerning the action of cinchophen was correct. In brief, if cinchophen acted on the end-product of nucleic acid metabolism as a part of its action on the central nervous system, it would be a simple matter to prove or disprove this point by giving the drug to animals whose kidneys had been disconnected from the central nervous system. Such experiments were undertaken. Fortunately the study of the uric acid excretion was made in addition to the allantoin excretion. It was found that the effect of cinchophen on the uric acid excretion was profoundly modified by denervation of the kidneys whereas the effect on allantoin excretion was only slightly changed.⁷ When cinchophen is given to the dog an increase in allantoin and uric acid excretion occurs without an increase in urinary volume. This seems to support Thannhauser's idea that the drug acts chiefly by increasing the concentration of uric acid in the urine. When, however, the drug is given to a dog with denervated kidneys, instead of causing an increase in uric acid excretion, a decrease occurs despite the fact that the volume of urine is always greater in the dog with denervated kidneys.⁸ It is evident from this that the action of cinchophen is not primarily concerned with concentration. Since the uric acid in the urine of a normal dog may be entirely exogenous, it seemed desirable to try the effects of the drug on a Dalmation hound which as a constitutional anomaly is unable to oxidize all uric acid into allantoin, occupying a position in this respect midway between other dogs and man. A chart of one of our experiments on a pure-bred Dalmation dog is shown herewith (figure 1). It will be seen that the effect of cinchophen on the excretion of uric acid is reversed as is the case in the normal dog. This reversal becomes progressively less as time goes on, and as regeneration of the renal nerves is completed the original reaction is restored. This experiment disposes effectively of the contention that there may be a difference in the handling of exogenous and endogenous uric acid, at least as far as the kidney is concerned. While these experiments show conclusively that the action of cinchophen on uric acid excretion is mediated through the nervous system, the increase in allantoin excretion was not explained. In order to understand this mechanism better it was decided to try to separate the sympathetic from the parasympathetic supply of the kidney by pharmacological means since this cannot be done satisfactorily by surgical methods.

To accomplish this two drugs are available. Ergotamine and atropine in adequate doses will block sympathetic and parasympathetic impulses re-

spectively It must be remembered that the latter connections of the kidney are partly through the celiac ganglion though some direct connections have been described ^{4,9} It seems likely from Feldberg's work,¹⁰ that preganglionic fibers are cholinergic and may be affected by atropine even though the impulses they carry terminate in so-called adrenergic postganglionic fibers Consequently, complete separation of the two parts of the sympathetic system is not possible and overlapping of results may occur However, by

FIG 1 Each point on abscissa represents the average 24 hour excretion of a three day period The figures opposite the dotted line curves indicate the order of the experiments after the kidneys had been surgically denervated

pharmacologic means plus the application of anatomic facts, the two systems can usually be separated by inference at least

The results of experiments ¹¹ employing either ergotamine or atropine simultaneously with cinchophen are compared with the effects of complete renal denervation in the accompanying table A consideration of these results indicates that the effect of cinchophen on allantoin excretion is mediated through the parasympathetic whereas that on uric acid excretion is mediated by the true sympathetic It becomes clear from this that uric acid excretion may be modified by the autonomic nervous system

If this be true, ergotamine in appropriate doses might affect uric acid excretion under certain conditions. In the experiments cited above ergotamine alone had no significant effect on either uric acid or allantoin excretion but did produce a diuresis. The same dose was able to modify the effect of cinchophen on uric acid excretion. Its action therefore is such that it may modify abnormal stimuli to uric acid excretion through the sympathetic. Any effect on uric acid excretion after the exhibition of this drug suggests the existence of abnormal sympathetic impulses through the renal nerves. This possibility had been foreseen many years ago by Thannhauser, and Harpuder¹² concluded that there was some diminution in uric acid excretion in normal individuals after the exhibition of ergotamine. However, his figures do not show highly significant changes. In a personal communication, Thannhauser has stated that he has always seen a diminu-

TABLE I

A summary of results obtained in the experimental studies of the uricosuric effects of cinchophen. In each case the comment indicates the results on this action when the indicated drug was given simultaneously with cinchophen.

| Action of Cinchophen | | |
|---|-----------------------------|-------------------------------|
| Modified by | On Excretion of | |
| | Uric Acid | Allantoin |
| Denervation of kidney Atropine Ergotamine | Reversed 0 Eliminated | 0 Eliminated Eliminated |

tion in uric acid excretion produced by the administration of ergotamine to gouty individuals and even the precipitation of an attack of gout. Hench,¹³ too, has mentioned two similar observations.

We have had a brief opportunity of studying one patient with pure gout under imperfect metabolic conditions. However, this patient is crucial in that careful investigation had revealed no other disease nor any involvement of the kidneys as such. The accompanying table shows the effect of a single injection of ergotamine on uric acid excretion in this patient. It seems significant that six or seven hours after the injection of the drug, reddening of and pain in the great toe occurred which the patient stated was precisely like his previous attacks which had occurred at sufficiently infrequent intervals to make the single observation of greater significance. The important result of the metabolic study is the diuresis produced by ergotamine with a smaller percentage increase in uric acid excretion. It is to be noted that in the four corresponding periods the creatinine excretion was in each period the same on the control day as on the experimental day, indicating in all

probability that the glomerular filtrate was of the same volume and that the differences produced by the injections of the drug concern reabsorption. Despite the absolute increase in uric acid excretion the concentration was diminished by ergotamine, indicating that the dose used was adequate to have an opposing effect to that of cinchophen. These facts might indicate that the gouty attack and uric acid excretion as such do not necessarily run hand in hand but none the less they are both connected with the autonomic mechanism which controls the concentration of uric acid in the urine. The effect of ergotamine on this gouty individual suggests that some impulses not normally present are acting on the uric acid excreting mechanism in this patient through the renal nerves, and that such impulses are capable of

TABLE II

Twelve hour excretion of J B S as affected by ergotamine. Identity of creatinine figures indicate similar volume of glomerular filtrate. Note the low concentration of uric acid accompanying the mild attack of gout. The blood uric acid remained unchanged, three samples in the first four hours ranging between 4.1 and 4.4 mg per 100 c c.

| Period Number | Time | Control Day | | | Ergotamine 1 mg s c at 8 a m | | |
|---------------|---------------|---------------|--------------|---------------|------------------------------|--------------|---------------|
| | | April 9, 1937 | | | April 7, 1937 | | |

modification by ergotamine in a similar fashion to its action on the stimulus provided by cinchophen.

If gout be a true functional disease of the autonomic nervous system, we should be able to discover in its symptomatology certain other features indicating such a disturbance. The diuresis of the gouty attack has been frequently observed. However, such patients have not been studied otherwise in relation to possible sympathetic disturbances. In the records of the Brigham Hospital, we have found 23 cases of gout without evidence of nephritis and these showed an average daily urinary volume of 1375 c c, as compared with 850 c c in random patients with nonmetabolic diseases in the hospital at the same time, indicating a continuing disturbance of the mechanism of water excretion. Since these cases were not studied at the time with this in mind, other clinical studies relating to the autonomic system are not available. Talbott, Jacobson and Oberg¹⁴ studied two patients and point out that a diuresis occurs before an attack of gout, however, their

tables show a continuing large urinary volume. It has been assumed that the diuresis of gout was an attempt to get rid of uric acid which the gouty kidney was unable to concentrate. However, it has been shown that the gouty kidney can concentrate uric acid as well as the normal¹⁵. Brugsch¹⁶ has emphasized the importance of the autonomic medullary centers in the control of purin metabolism.

The data collected here suggest that the etiology of gout may well be sought in functional disturbances of the vegetative nervous system involving especially the innervation of the kidney.

LYMPHOSARCOMA CELL LEUKEMIA *

By RAPHAEL ISAACS, *Ann Arbor, Michigan*

It has been observed frequently that the blood of patients with lymphosarcoma may become leukemic. This syndrome has been characterized as leukosarcoma by Sternberg¹ or as lymphosarcoma terminating in lymphatic leukemia^{2, 3, 4}. Flashman and Leopold⁵ noted 107 cases of this type in the literature and described an additional case. On the basis of a lymphosarcoma presumably terminating in lymphatic leukemia, numerous speculations have been published concerning the relationship of these two conditions. A careful cytological study of the cell types in this form of leukemia has shown, however, that the cells are not lymphocytes, but lymphosarcoma cells, so that the condition is a true lymphosarcoma cell leukemia.

MATERIAL AND METHODS

Of 43 patients with known lymphosarcoma, 15 developed a leukocytosis during the course of the disease. This group comprised 10 males and five females. There were eight positive biopsies and six autopsies. The ages of the patients ranged from six to 70 years, with a fairly even distribution in the intervening decades, except that between 21 and 30 years, which included one third of the patients. Warthin⁶ noted leukemic transformation in nine cases of lymphosarcoma, out of a group of 134 biopsies.

To note how a lymphosarcoma cell would appear if it was in the blood stream, pieces of fresh lymphosarcoma glands were stirred in blood serum, and films were made of this suspension. These were stained with Wright's stain alone or preceded by brilliant cresyl blue while the cells were in the moist state.

THE LYMPHOSARCOMA CELL

The lymphosarcoma cell in the blood stream is usually mistaken for a lymphocyte. There are certain differentiating features, however, the most marked being the peculiar characteristics of the nucleolus. This is usually eccentrically placed, single, very rarely multiple. In the films made on brilliant cresyl blue containing cover glasses, later stained with Wright's stain, the nucleolus stands out as a sky blue, round area, surrounded by a deep, blue black rim of chromatin which is piled up around it (Figure 1). In the true immature lymphocyte or lymphoblast, under these conditions, the

* Presented to the Michigan Academy of Science, Arts and Letters, March 8, 1935, and, in abstract, to the American Society of Experimental Pathology, Washington, March 25, 1936 (Arch Path, 1936, *xxii*, 287).

From the Thomas Henry Simpson Memorial Institute for Medical Research, University of Michigan, Ann Arbor, Michigan.

nucleolus appears as a light blue "hole" or area in the chromatin structure, without the heavily staining rim. The nucleoli are more likely to be multiple in the immature lymphocytes or lymphoblasts than in the lymphosarcoma cell.

The lymphosarcoma cell, in films, varies in size from 7.5 by 9 microns to 12 by 13.5 microns. The nucleus is usually oval or oblong, occasionally being egg shaped (thicker at one end) in films. Kidney shaped or notched forms are common in some specimens. The stained chromatin is coarsely reticular and somewhat spongy in structure and the chromatin around the edge is thickened into a fairly definite nuclear wall, differing in this respect from the monocyte. The cytoplasm of the cell is sparse, deeply basophilic, and with the brilliant cresyl blue, Wright's stain, appears as a fine, blue lace-work.

In sections of fixed tissue, the lymphosarcoma cell is large and round, resembling the lymphoblast in size and proportion of practically non-granu-

FIG 1 Cells from peripheral circulation. Stained supravitaly with brilliant cresyl blue and counterstained with Wright's stain. (Camera lucida drawings) 1-4 normal blood. 1 Normal red blood cell, for size comparison. 2 Small lymphocyte. 3 Large lymphocyte. 4 Large immature lymphocyte, with several small nucleoli. 5, 6, 7 Cells from lymphosarcoma cell leukemia. 8 Lymphocyte from lymphatic leukemia.

lar cytoplasm. The nucleus may be irregular in size and shape, many showing indentations or lobulation.

These cells were studied supravitaly by Wiseman⁷ who found that unlike mature lymphocytes, they did not show motility, although both types did not show evidence of phagocytosis. The mitochondria were described as dust-like, as compared to the large rods and spheres of the mature lymphocyte and the small spheres of the lymphatic leukemia cell. Deep scarlet neutral-red vacuoles, 1 to 10, were present at the periphery of the nucleus in the "sarcoma cell" although they were absent in the leukemic cell and, when present in the mature lymphocyte, they stained rose red.

THE BLOOD

There appear to be two phases of the blood in patients with lymphosarcoma—an aleukemic and a leukemic phase. In the aleukemic phase, the

leukocyte count varies from 6,000 to 10,000 per cubic millimeter with 30 to 40 per cent "lymphocytes" Many of these cells are not lymphocytes, but lymphosarcoma cells The percentage varies from 3 or 4 to 25 or 30 in this group In the leukemic phase, the count rapidly increases to an average of $70,000 \pm 43,200$ per cubic millimeter, the highest count in this series being 156,000 per cubic millimeter As the count increases, the bulk of the cells are lymphosarcoma cells, which in some cases form 98 per cent of the total

As the leukemic process progresses, anemia becomes more marked, the average red blood cell count being around 2.5 million per cu mm In some patients it reached a much lower level (0.8 to 1.0 million) The color index was most frequently around 1 or slightly below The blood platelets were increased in number in the early stages, but decreased in the late stages

CLINICAL COURSE

In most of the patients, enlargement of lymph nodes was the first sign noted Visible tumors in the neck region were the first evidence in three patients, inguinal nodes in two, mediastinal (cough, dyspnea, pleural effusion) in three, abdominal symptoms in two, sore throat in four, weakness in two and submaxillary enlargement in one Symptoms, in order of their frequency, were weight loss (average 15 pounds), fever, bleeding (petechiae, hemoptysis, hematuria, epistaxis, hematemesis, gross bleeding from mucous membranes, retinal hemorrhages), joint pains, pulmonary and hilar lesions (roentgen-ray changes, pleural effusion, dyspnea, chest pain, cough), allergic symptoms, herpes, skin lesions (toxic erythema, erythema multiforme), bone lesions, facial palsy, diplopia, local edema Albuminuria (trace), during some stage of the disease was common The spleen size varied from 15 to 23 centimeters (average 16.5 cm), and at autopsy the weights varied from 490 to 700 grams The spleen was palpable in seven patients

With the onset of the leukemic phase, fever was common (100 to 105° F) Terminally, 104° to 107° F were noted Lung involvement was not always definitely indicated on the roentgen-ray plates, although autopsy in some of these patients showed infiltration of the alveolar walls and of the perivascular and peribronchial tissue with lymphosarcoma cells This type of lesion was most common in patients dying in the leukemic state, whereas in two who were aleukemic on the day of death, the lungs were not involved The degree of leukemia was more parallel to the lung involvement than to the degree of peripheral lymph node enlargement

The duration of the disease varied from 2.5 to 36 + months The duration of the leukemic phase varied from two days to 60 days in eleven patients in whom approximate data were available One patient, however, gave a history of a leukemic blood picture (94,000 per cu mm), diagnosed as lymphatic leukemia, for over seven years This patient had a white

blood cell count of 37,000 when first observed at this clinic, with 84 per cent lymphosarcoma cells. He died 27 days later. The maximum count was 73,000. The average duration of the leukemic phase in all of the other patients was 26 days.

Nine patients gave a history of one or more of the common childhood diseases. Of the others, three gave a history of a symptom complex which they were told was influenza.

LYMPHOSARCOMA AND PREGNANCY

One patient with lymphosarcoma showed a remission during a period of pregnancy. The patient, a 31-year-old woman, was first studied after she had had cervical and axillary glandular enlargement for 18 months. Her blood count at that time was as follows: Red blood cell count 3,500,000 per cu mm, white blood cell count 47,800, hemoglobin 67 per cent (Sahli), 9.38 grams per cent, atypical "lymphocytes" 65 per cent, blasts 0.5 per cent. She became pregnant six months later, and during the third month she returned to the clinic for examination. At that time her red blood cell count was 4 million per cu mm, white blood cells 7,100 per cu mm, hemoglobin 12.93 grams per cent, polymorphonuclear neutrophils 71 per cent, large lymphocytes 15 per cent, small lymphocytes 9 per cent, monocytes 5 per cent. The adenopathy had practically disappeared. A perfectly normal child was born in due course of time, and eight months after this the blood count was still normal, but lymphosarcoma cells were noted on the blood films. About nine months after this, the patient returned in complete relapse, with a red blood cell count of 800,000 per cu mm, white blood cells 4,200, hemoglobin 2.88 grams per cent. Lymphosarcoma cells, 27 per cent, and one blast were noted. She received two blood transfusions and had another remission. An examination four months later showed her red blood cells at a level of 3,600,000 per cu mm, white blood cells 6,100 and hemoglobin 75 per cent (Sahli) (10.5 grams per cent), "lymphocytes" 59 per cent.

EFFECT OF ROENTGEN-RAY IRRADIATION

In 11 of the patients the leukemic phase started after roentgen-ray therapy, in two no roentgen therapy was given, and in two it is uncertain whether the patients had received roentgen therapy before they reported to the hospital or not. A decrease in the number of leukocytes followed roentgen-ray therapy during the leukemic phase, in 8 patients, with severe leukopenia (3,500, 1,800 and 350 per cu mm) developing in three patients. In five patients there was a subsequent increase in number after the initial decrease. There appeared to be two stages in the effect of roentgen-ray therapy, an initial decrease in the number of leukocytes, followed by a marked and rapid increase. Thus in one man with a leukocyte count of 50,000 per cu mm (96 per cent lymphosarcoma cells), 2800 r were given over 12 positions from May 20 to June 4. On the last day the count was

33,000 per cu mm Two days later the count was 156,000 per cu mm and the patient died In another patient the initial count was 10,500 leukocytes per cu mm On five successive days, 150 r were given The leukocyte count fell to 5,500 per cu mm It then rose gradually to 15,200 with 66 per cent lymphosarcoma cells 43 days later Three days before death, which followed in two weeks, the count was 92,000, with 85 per cent lymphosarcoma cells A third example is that of a patient with 7,800 leukocytes per cu mm, who received 1,200 r over a five day period At the close of the treatments the leukocyte count was 6,800 per cu mm An observation 41 days later showed that the count had increased to 50,000 per cu mm and three days later to 70,800 per cu mm The patient died within four weeks

PATHOLOGICAL CHANGES IN THE ORGANS

Autopsy studies of the organs of patients dying during the leukemic phase showed transformation, in varying degrees, of all lymphoid tissue in the body, into the lymphosarcoma type The lymphoid follicles of the intestine and colon, as well as the tonsil showed this change There was marked invasion of the bone marrow and subperiosteal extension, which also involved the surrounding tissues All of the organs showed invasion with lymphosarcoma cells Among those showing perivascular or tissue infiltration were the brain, capsule of the pituitary, the fatty envelope of all the organs (heart, kidneys, aorta), the myocardium, beneath the epicardium, bronchi, pulmonary alveolar walls, thyroid, esophagus, thymus, spleen, diaphragm, stomach, liver, gall-bladder, adrenal, kidney, ureter, skin, testes, epididymis, seminal vesicles and vas deferens The skull, when involved, showed osteolytic lymphosarcomatous infiltration

DISCUSSION

The frequent occurrence of the leukemic state of lymphosarcoma after roentgen-ray therapy is of interest in connection with the observations of Krebs, Rask-Nielsen and Wagner⁸ on the production of a "leukosarcomatosis" (aleukemic and leukemic) in white mice after irradiation They found that the leukemic phase developed late in the course of the disease, and that, as in the cases cited here, the prognosis was bad

In view of the tendency of the lymphosarcoma cell to invade the tissues, it is not surprising that some of the cells enter the blood stream However, it appears that the number does not reach leukemic proportions until there is extensive growth in moving organs, as the lungs This phenomenon is similar to that found in other types of leukemia (Isaacs⁹)

SUMMARY AND CONCLUSIONS

1 The characteristics of 15 cases of lymphosarcoma cell leukemia are given

2 The lymphosarcoma cell has characteristic cytologic features which facilitate its recognition in the blood stream. This cell type may constitute 4 to 98 per cent of the leukocytes in the peripheral circulation.

3 The leukemic phase is usually ushered in with exacerbation of symptoms and fever.

4 The leukocyte count may reach a maximum of from 23,000 to 156,000, and there is progressive anemia and thrombocytopenia.

5 The duration of the leukemic phase varies from two to 60 days (average 26 days) although one patient had a history of leukemia for over seven years.

6 There may be relapses and remissions, but the prognosis is poor. A temporary remission may be induced by roentgen-ray therapy, but this is followed by a relapse and death.

7 The disease appears to be a true lymphosarcoma cell leukemia, rather than lymphosarcoma turning into lymphatic leukemia.

THE FLOW AND CONCENTRATION OF BLOOD AS INFLUENCED BY ERGOT ALKALOIDS AND AS INFLUENCING MIGRAINE *

By WILLIAM G LENNOX, M D, and HILDEGARDE C LEONHARDT,
Boston, Massachusetts

IN about 90 per cent of patients suffering from an attack of migraine headache, the injection of ergotamine tartrate causes complete disappearance of the pain and other symptoms ¹ In the case of the more recently isolated alkaloid of ergot, ergonovine, clinical results are not so striking In our 54 patients who received injection of the drug, pain was stopped in 39 per cent and was improved in a further 40 per cent ² The beneficial action of ergot seems to be specific for headaches of the migraine type ³ These welcome therapeutic results led us to investigate the physiological effects of these ergot derivatives

In this communication we report the action of ergotamine and of ergonovine on the speed of flow and on the concentration of blood as revealed by measurement of blood gases No observations of blood flow have been reported for ergonovine As for ergotamine tartrate, Lennox, Gibbs and Gibbs,⁴ by means of a thermoelectric flow recorder inserted in an internal jugular vein of migraine patients, obtained records showing an increase of cerebral blood flow after intravenous injection, presumably a result of the coincident increase in blood pressure On the other hand, Herrick,⁵ in dogs, obtained large increases in blood pressure but a decrease in blood flow which, on the average, was only one-fourth its initial value Presumably, the difference in results can be accounted for by the fact that his dogs received a dose three or four times that used by us in human subjects

Because epinephrine has been considered pharmacologically as the antagonist of ergotamine, parallel observations were made with this drug

MATERIALS AND METHODS

Epileptic and other patients on the Neurological Service at the Boston City Hospital were used for these observations Subjects were in bed but not fasting Blood was drawn from the arm without stasis under oil, chilled and analyzed at once in the apparatus and by the technic of Van Slyke ⁶ After the preliminary blood sample was taken, the subject was given either ergotamine tartrate, 0.5 mg intravenously, or ergonovine, 0.6

* Received for publication July 29, 1937

From the Neurological Unit of the Boston City Hospital and the Department of Neurology of Harvard Medical School, Boston, Mass The research was aided by the Josiah Macy, Jr Foundation

mg intravenously or 12 cc by mouth, or epinephrine, 0.1 mg subcutaneously^{*} Records were kept of the subject's blood pressure and pulse rate and of his symptoms The second blood sample was taken after a lapse of from 30 to 60 minutes (the interval required for ergotamine to stop a headache) After epinephrine injection, the interval was 40 to 70 minutes, the effort being to secure blood while the reaction was at its height

Ordinarily, an alteration in blood flow would be shown by an alteration of oxygen content, but when the concentration of red cells is changing, measurement of the oxygen saturation also is necessary The percentage of saturation was obtained by dividing the oxygen content of the blood by its oxygen capacity Changes in the oxygen capacity of the blood represent changes in the concentration of the red cells Results will first be stated, then discussed

EFFECT ON OXYGEN SATURATION OF VENOUS BLOOD

Ergotamine Tartrate Fourteen observations were made of changes in the blood gases of the venous blood of the arm following the intravenous injection of ergotamine In all these observations there was a wide scattering of individual results, but nearly all were in the same direction After injection of ergotamine, in three instances there was a decrease of oxygen saturation and in 11 an increase The average change was an increase of 8.1 per cent (i.e., from an oxygen saturation before injection of 63.5 per cent to 71.6 per cent saturation after injection) (See the accompanying table) The percentage increase in the average oxygen saturation of the blood (12.7 per cent) was not as great as the percentage increase in its oxygen content (17.7 per cent), because the oxygen capacity of the blood also increased

Ergonovine Eighteen patients were given ergonovine (*Ergoklonin*) In six instances, administration was intravenous, and in 12 instances, by mouth The average oxygen saturation of venous blood showed a definite increase of 10.6 per cent when the drug was injected and of 4.2 per cent when it was ingested A change greater after intravenous injection than after ingestion was to be expected The greater effect of ergonovine than of ergotamine is explainable by the larger dose contained in an ampule of ergonovine

Epinephrine This drug was injected in 13 instances Results were less uniform than in the case of ergot A decrease in the oxygen saturation

^{*} Ergotamine tartrate (*Gynergen*) was supplied by the Sandoz Chemical Works, Inc., of New York, and ergonovine (*Ergoklonin*), by John Wyeth and Brother, Inc., of New York Each of these firms also contributed funds for the research Ergonovine was so named by the Council on Pharmacy and Chemistry of the American Medical Association *Ergoklonin* is a trade name The preparations of *Ergoklonin* furnished us, being brownish in color, presumably contained ingredients other than ergonovine, which in solution is clear *Ergoklonin*, however, had an action similar to other preparations of ergonovine in the clinical and laboratory tests which we used, 0.2 to 0.3 mg of ergonovine is equivalent to about 0.5 mg of ergotamine

FIG 1 The average and individual measurements of the change in the oxygen capacity of venous and arterial blood following the administration of ergotamine tartrate, ergonovine (*Ergoklonin*), and epinephrine. The ordinant represents the absolute change in the oxygen capacity in volume per cent. The columns indicate the average measurements for the group, and the dots, the individual measurements. The ergotamine was given intravenously in all cases. The *Ergoklonin* was given by mouth except for those experiments in the venous column which were marked by crosses. Crosses in this compartment indicate medicine given intravenously. The epinephrine in all cases was given subcutaneously.

occurred in four of the 13 observations and the average change was an increase of 5.8 per cent

Discussion In resume, the increase in the average absolute per cent saturation of venous blood for the various groups, as well as the percentage increase over the preliminary measurements was as follows

| | | | Absolute Increase Per cent | Percentage Increase |
|---------------------|-----|----------|-------------------------------|------------------------|
| Ergotamine tartrate | I V | 14 cases | 8.1 | 12.7 |
| Ergonovine | I V | 6 cases | 10.6 | 18.6 |
| Ergonovine | P O | 12 cases | 4.2 | 8.0 |
| Epinephrine | S C | 13 cases | 5.8 | 8.9 |

An increase in the oxygen saturation of venous blood means either a decrease in the consumption of oxygen on the part of the tissues through which the blood passes or an increase in the rapidity with which the blood flows through the part. Epinephrine increases oxygen consumption, whereas in normal persons, ergotamine does not.⁷ However, most subjects were more restless after injections than before, and their metabolic rates were presumably increased, therefore the increase in the speed of blood flow through the arms, especially in the case of epinephrine, was probably greater than the measurements indicate. An increased cerebral blood flow following injection of epinephrine⁸ and of ergotamine⁴ has been demonstrated by other methods. The increased cardiac output from epinephrine is well known.

Effect on Oxygen Saturation of Arterial Blood Thirty-one observations were made of arterial blood before and after the injection or ingestion of these three drugs. As would be anticipated, changes in the average oxygen saturation were negligible. Ergonovine given by mouth and epinephrine injections caused no significant alterations. After injection of ergotamine, the oxygen saturation decreased by 2.2 per cent. This decrease did not, of course, indicate a decrease of blood flow, the blood being arterial, but was due to an increase in the oxygen capacity of the blood. The oxygen content of the blood did not keep pace with the increase in its capacity, due possibly to an increased speed of blood flow through the capillaries of the lungs which allowed less time for the transfer of oxygen to the blood.

Effect on Oxygen Capacity of Venous Blood After injection of ergotamine, the oxygen capacity of venous blood was increased in all experiments save one. The average increase was 0.90 volumes per cent (from 19.46 volumes per cent before, to 20.40 volumes per cent after the injection). Increase of a comparable magnitude occurred after ergonovine (0.84 volumes per cent when given intravenously and 0.86 volumes per cent when given by mouth). The changes after injection of epinephrine were variable and the average increase was only 0.15 volumes per cent. Average results appear in the table and both average and individual results are indicated in the figure.

Effect on Oxygen Capacity of Arterial Blood The average increase in the oxygen capacity after ergotamine injection was 0.98 volumes per cent, and after epinephrine injection, 0.11 volumes per cent. After ergonovine taken by mouth, the average increase was 0.47 per cent which was less than the increase which occurred in venous blood. The average changes in arterial blood after ergotamine and epinephrine were almost identical with those occurring in venous blood.

Consolidating the observations for venous and for arterial bloods, the oxygen capacity of blood was increased by these drugs on the average as follows

| | | | In Vol Per cent | Percentage Increase |
|-------------|-----|----------|--------------------|------------------------|
| Ergotamine | I V | 27 cases | 0.94 | 4.8 |
| Ergonovine | I V | 6 cases | 0.84 | 4.4 |
| Ergonovine | P O | 22 cases | 0.68 | 3.5 |
| Epinephrine | S C | 21 cases | 0.13 | 0.6 |

Quantitative results therefore differ, the increase being of a different order for ergot derivatives than for epinephrine.

Edmunds and Nelson⁹ have reported that the subcutaneous injection of epinephrine in 10 dogs caused an average increase of 23 per cent in the number of red cells of capillary blood. The relatively small change which we observed is probably due to the fact that they injected 50 to 70 times the amount of epinephrine we used. They attribute the polycythemia both to a loss of blood plasma and to the addition of red cells swept from the bone marrow. We have no direct evidence as to which of these changes was responsible for the increased concentration of arterial and venous blood which follows the administration of ergot derivatives.

Inspection of the table shows that, irrespective of changes in the average oxygen content of the blood, the average carbon dioxide content decreased in each of the four different experimental procedures. We believe this decrease was due to increased pulmonary ventilation associated with the restlessness which followed the injection of the drugs.

Discussion We have observed then that the ergot derivatives, ergotamine tartrate and ergonovine, cause moderate increase in the speed with which blood flows through the arm as measured by the oxygen saturation of the venous blood. This increase presumably is due to the increase in blood pressure which occurred in these cases.² The increased pressure presumably followed a mild constriction of peripheral arteries. Pool and Nason¹⁰ observed constriction of dural and skin vessels in animals. In order to account for increased blood flow, the peripheral vasoconstriction, if generalized, must be more than counterbalanced by the cardiac output. The beneficial results of ergot cannot be attributed solely to the increased blood flow, because similar increase in flow took place when adrenalin was injected, but only in a minority of cases is the use of adrenalin followed by relief of migraine headache.

There was an increase in the concentration of the blood following the administration of ergot. The average degree of concentration differed for the three drugs used, the order being ergotamine, ergonovine and epinephrine. This is the same order in which these drugs are effective in stopping migraine attacks. In fact, the quantitative differences between the ergot fractions on the one hand and epinephrine on the other are so great as regards their effect on headache and on the concentration of blood that alterations of blood concentration might be suspected of playing a dominant rôle in migraine headache. We do not believe, however, that relief of migraine attacks is due simply to a concentration of red cells in the blood. If it were, therapeutic results in migraine would have been reported in conditions associated with dehydration of the blood, such as starvation, purgation and profuse sweating.

There is indication, rather, that ergot in the therapeutic doses employed, causes a "tightening up" of the blood vascular system, an increased tone to arteries whose tone may have been impaired, increase in blood flow and possibly of cardiac output, and a decreased volume along with an increased viscosity of the blood. These observations would seem to dovetail with those of Wolf,¹¹ who, after ergotamine injection, observed a 50 per cent reduction in the pulsation of temporal arteries of patients having migraine headache, the reduction paralleling in time the relief from headache. The increase of spinal fluid pressure which follows injection of ergot, reported by Pool, von Storch and Lennox,¹² might be due to a transfer of fluid from cerebral capillaries. Also, Pool and Nason¹⁰ observed consistent constriction of dural and skin vessels after ergotamine, whereas pial vessels behaved variably. The dural vessels are presumably more at fault in migraine headaches than those in the cerebrum. Our observations, therefore, may form a link in the explanation of the mechanism of migraine headaches when such explanation is complete. The final chain of reasoning must, however, be distinctive for migraine as contrasted with non-migraine headaches, and must explain not only the headache, but the visual, the sympathetic and the peripheral sensory disturbances which form a portion of the migraine syndrome.

SUMMARY

Ergotamine tartrate was administered to 27 subjects, ergonovine to 28 and epinephrine to 21, in order to observe the effect on the flow and the concentration of blood as measured by changes in the concentration of blood gases.

The parenteral administration of ergotamine, of ergonovine and of epinephrine produced a percentage increase in the average oxygen saturation of venous blood from the arm of 12.7 per cent, 18.6 per cent and 8.9 per cent respectively.

The ergot derivatives injected intravenously produced a definite increase in the oxygen capacity of both venous and arterial blood, the combined percentage increase being for ergotamine, 48 per cent, and for ergonovine, 44 per cent. In contrast, epinephrine caused insignificant increase, 0.6 per cent.

Therefore, these ergot derivatives, like epinephrine, cause increase in the rate of blood flow through the peripheral tissues. Unlike adrenalin, ergotamine and ergonovine concentrate the blood. The specific effect of ergotamine and of the less effective ergonovine in relieving migraine headache may be partially explained by their action in increasing the tone of arteries. Increase in blood pressure and blood flow and decrease in blood volume may be the result of the increase in arterial tone. These observations may form a link in the chain of reasoning which ultimately will explain the mechanism of migraine.

Effect of Ergotamine Tartrate, of Ergonovine, and of Epinephrine on Blood Gases

| Arm Vein | No of Cases | O ₂ Content Vol % | O ₂ Capacity Vol % | O ₂ % Saturation | CO ₂ Content Vol % |

INTRAVENOUS LIVER EXTRACT IN THE THERAPY OF PERNICIOUS ANEMIA, REPORT OF A CASE *

By H B MULHOLLAND, M D , F A C P , *University, Virginia*

It is a common observation that patients with pernicious anemia may fail to respond to the oral administration of liver, liver extract and ventriculin, and that these same patients will respond promptly to an extract given intramuscularly. Satisfactory and more rapid improvement in the patient's blood has been frequently noted after intravenous injection of specially prepared liver extract^{1, 2, 3, 4, 5}. However, this intravenous therapy is not in general use because of the side reactions noted in many cases.

The case of pernicious anemia reported in this paper is of interest because on the first admission the patient responded in a characteristic manner to the administration of liver extract intramuscularly and subsequently he had a relapse. On further treatment a progressive aplastic state continued despite the administration of oral liver, intramuscular extract, ventriculin and blood transfusions. Finally liver extract given intravenously resulted in a prompt and complete remission.

CASE REPORT

E L J, white farmer, aged 62, admitted to the hospital on November 19, 1934, complaining of weakness and generalized aching of three weeks' duration. Five years before his admission, while working for the State Highway Department he noted an increasing weakness which progressed finally to the point of difficulty in walking. There was no numbness or tingling. He was admitted to a Washington hospital where a diagnosis of pernicious anemia was made and he began taking liver by mouth. After a year's rest he was again employed and continued work for eight months. At the end of this period he reported that while cranking a car he felt something "give way inside of him," and that he had been unable to work since then. The patient's therapeutic regime was now changed to liver extract per os and later it was given intramuscularly. His treatment had been most irregular and he described periods of weakness coinciding with the times in which he had no therapy. Three years ago a lumbar puncture was done and he stated that he has been unable to walk since that procedure. Four blood transfusions had been administered during the past year. Three weeks before admission his local physician advised hospitalization because of weakness, palpitation of the heart and poor appetite.

The physical examination revealed an undernourished, elderly, pale man. The mucous membranes were pale and the sclera lemon tinged. The tongue was smooth and glistening. The heart, lungs and abdomen were normal. The blood pressure was 110 mm of Hg systolic and 45 diastolic, pulse 112, and there was slight pitting edema of the shins. A bilateral hydrocele was present. The patellar reflexes were hyperactive, ankle clonus was present and there was a positive Babinski sign. The vibratory sense was absent below the knees. The patient could not walk.

* Received for publication August 4, 1937

From the Department of Internal Medicine, University of Virginia Hospital

Laboratory examinations showed the following Hemoglobin 22 per cent (Dare), red blood cells 1,900,000, white blood cells 3,000, with band cells 4 per cent, segmented 51 per cent, small lymphocytes 43 per cent, large mononuclears 2 per cent. The platelet count was 137,000, the reticulocytes 15 per cent, color index 52, volume index 42, and the icterus index 15. The smear showed the red cells to have a marked anisocytosis with many microcytes, a few macrocytes, moderate poikilocytosis, and a moderate diffuse polychromatophilia was present. One normoblast was seen. No free hydrochloric acid was present in the stomach contents after the injection of histamine. The Wassermann and Kahn were negative.

From the history and findings a diagnosis of pernicious anemia was made and intramuscular liver therapy inaugurated. After one week of treatment the volume index changed to 12 and the color index to 12. The patient responded typically to this therapy as indicated in chart 1. Throughout his stay in the hospital he was

CHART 1

given iron and ammonium citrate, 90 grs daily. On discharge 41 days after admission he had improved in all respects, and he could move his legs without difficulty.

After leaving the hospital this patient took his liver extract intramuscularly (2 cc) once weekly for a while, then the interval between treatments became lengthened to every two weeks and finally once a month. He again became progressively weaker, with all of his old symptoms returning. On December 29, 1935, the patient was readmitted. In the period between the two admissions he had not been able to walk. The physical examination showed that the patient was again pale and thin. The blood pressure was 96 mm of Hg systolic and 54 diastolic, and the knee jerks hyperactive, ankle clonus present with bilateral positive Babinski. On the whole he was in the same physical state as on the previous admission. Laboratory

examinations showed a hemoglobin of 35 per cent (Dare), red blood cells 1,740,000, white blood cells 2,800, and the differential essentially the same as on the last admission. The smear showed many macrocytes and a few poikilocytes. The color index was 1.3, volume index 1.4, reticulocytes 0.2 per cent, and the icterus index 10.5. A mild cystitis was also found to be present. A gastrointestinal roentgen-ray series was negative.

The patient was given 10 cc of concentrated intramuscular liver extract (Eli Lilly) followed by 2 cc of the same preparation every four days. In spite of this therapy there was very little reticulocyte response, the red count and hemoglobin decreased and the patient showed a progressive loss of strength and appetite. Parke Davis' intramuscular extract was then given and blood transfusions, liver by mouth and ventriculin were all tried with only temporary effect. Finally it was decided to give an intravenous preparation*. Twenty cubic centimeters were administered intravenously very slowly and this was followed by a chill and a temperature of 104° F. Following this the patient showed improvement in his condition, the reticulocytes rose and the blood picture in general showed evidence of the influence of the active principle in liver. On each subsequent injection of liver intravenously (five in all) the reactions became decreasingly severe with only slight flushing of the face and a little shortness of breath. Iron and ammonium citrate (90 grains daily) was given from the day of admission to the day of discharge. The essential data are given in chart 2. The patient was discharged 120 days after

CHART 2

admission in good general condition, with a normal blood count, but he was still unable to walk. He is being maintained at home in a good state of health with a normal blood picture by an intramuscular injection of 2 cc of liver extract once a week.

* An intravenous extract prepared by Parke Davis Co was obtained through the courtesy of Dr Raphael Isaacs, Ann Arbor, Mich.

COMMENT

In a review of the literature no mention was found of a similar case of pernicious anemia. Rhoads and Miller⁶ cite two cases of sprue that failed to respond to intramuscular extract but recovered promptly when the extract was given intravenously. Castle et al.⁷ also emphasize the importance of intensive parenteral therapy in this condition. One can only speculate with respect to the failure of this patient to respond to the usual therapeutic procedures used in treating pernicious anemia. The only evidence of infection was found in the bladder and it seems doubtful that this was sufficient to prevent an adequate response.

Minot⁸ has called attention to the importance of adequate quantitative treatment in pernicious anemia, and it is possible that in this case the amount of liver used was not sufficient even when given intramuscularly. The only alternative explanation that can be offered is that the extract was not utilized which seems doubtful in view of the subsequent control by the intramuscular preparation. It is thought, however, that the case presents a method of dealing with an interesting therapeutic problem which might be useful in similar situations.

FAMILIAL SHIFT TO THE LEFT OF THE LEUKOCYTES (PELGER'S NUCLEAR ANOMALY OF THE LEUKOCYTES), WITH REPORT OF A CASE^{*}

By WILDER TILESTON, M D , *New Haven, Connecticut*

IN 1928 Pelger⁶ reported to the Dutch Pathological Society at Amsterdam two cases showing an anomaly of the leukocytes, hitherto undescribed in the literature. The neutrophils, eosinophils and basophils all showed a large percentage with non-segmented nuclei, and the segmented forms were represented almost exclusively by those with only two nuclei. Furthermore, the nuclei differed from those met with in the ordinary shift to the left of infectious diseases, in that they had a remarkably regular shape with even contours. The protoplasm of the neutrophils on the other hand showed fine even granulations, of the type seen in mature cells. His first case was a woman who suffered from cachexia of obscure origin, and died of a terminal pulmonary infection, there was no autopsy. His second patient was a man with splenomegaly, material obtained by puncture of the spleen was injected into a guinea-pig and caused tuberculosis in the animal. Pelger believed that the anomaly of the leukocytes was pathological, in some manner connected with tuberculosis, and of bad prognostic import.

Three years later Huet⁴ discovered a similar hemogram in a niece of Pelger's first patient, and investigating other members of the family, found it in them also. He was therefore the first to recognize the familial character of the anomaly, and since it was present in healthy people, he declared it to be without pathological significance. Huet also reported two other families with this condition, there was no interrelationship between these families.

Other reports soon followed, so that up to the present time there have been recorded five such families in Holland, three in Germany, one each in Switzerland, Czechoslovakia, and the United States. It has been shown that the anomaly is inherited as a dominant Mendelian character, not sex-linked.

The following case, taken from the writer's private practice, seems worthy of record. It is the second to be reported in this country, and the first involving a person of English ancestry, Peterson's⁷ publication having concerned a Chinese family.

CASE REPORT

The patient, a lawyer now 73 years of age, has been under the writer's care for the past 26 years. In January 1918 he had an attack of lobar pneumonia of moderate

^{*} Presented at the Annual Meeting of the Association of American Physicians, May 5, 1937

severity, with high fever and terminating by crisis, the leukocyte count was 16,600 with 82 per cent neutrophils. In November 1918 he had influenza, with a temperature of 103 degrees and a leukocyte count of 3,500, no differential count was made. These facts are interesting as indicating a normal reaction to infection on the part of the bone marrow.

For the remainder of this long period he has had no serious illnesses, and is now in good health and active in the practice of his profession.

Five years ago he had an attack of syncope, the cause of which was undetermined, and a routine examination of the blood disclosed the fact that, although there were no signs of infection and the total leukocyte count was normal, more than half of the neutrophils were non-segmented or staff forms, and that the nuclei of the remainder had, almost without exception, only two lobes. This curious condition has persisted ever since, with little change in the relative proportions (table 1). Most

| 6-2-37 | 4.7 | 88 | 7,800 | 43 | 21 | 27 | 5 | 3 | 1 |

of the smears have shown no nuclei with more than two lobes, rarely one with three lobes has been present (up to 1.5 per cent in the differential count), but never any with more than three lobes.

The appearance of the nuclei of the neutrophils is unusual, the contours being smooth and regular, in contrast with the irregular shapes seen in the ordinary shift to the left, and in normal blood. A fair number of the non-segmented forms (up to 12 per cent of all neutrophils) might be classified as "juvenile," by reason of their broad kidney-shaped nuclei, no myelocytes were encountered. The segmented cells have two oval or round nuclei, connected by a fine thread.

The protoplasm of the neutrophils shows no abnormalities, toxic granulation and vacuolization being uniformly absent.

The eosinophils are affected in a similar way, but to a less marked degree, a differential count of 100 eosinophils showing 38 per cent non-segmented, 62 per cent two-lobed, none with more than two lobes. It should be noted that in normal blood segmentation of the eosinophils is not carried out to the same extent as it is in the case of the neutrophils, 76 per cent having two nuclei, and only 19 per cent more than two. However, staff cells normally make up only 3 per cent of the total, according to Zundel.¹⁰

FIG 1 Photomicrographs of polymorphonuclear leukocytes No 5 shows an eosinophile, others are neutrophiles Leishman stain, magnification approximately 800

It was difficult to determine whether the basophiles were involved or not, on account of the scarcity of these cells, and their frequent failure in normal blood to show clear-cut segmentation into several nuclei

When treated with Goodpasture's stain, all of the neutrophils showed abundant oxidase granules. In a supravital preparation examined by Dr R M Thomas, all of the granulocytes showed motility, and no abnormal granulations were present

An attempt to estimate the phagocytic activity of the leukocytes, made by Prof George H Smith, disclosed an interesting phenomenon, hitherto undescribed in this condition, on centrifugation of the ovalated blood, the leukocytes gathered together into a sticky mass, so cohesive that it was impossible to draw them up into a pipette, or smear them on a slide. No explanation of this curious behavior was forthcoming

The differential count was normal, so far as lymphocytes, monocytes and basophiles were concerned. A tendency to eosinophilia (up to 10 per cent) was present, for which no cause was apparent, it is interesting to note that a grandnephew of the patient, otherwise healthy and not showing the anomaly, had 18 per cent eosinophiles. In some of the cases reported in the literature eosinophilia has been present but not often enough to suggest any connection with the anomaly

The red count, hemoglobin, and total leukocyte count were within normal limits, apart from a trifling anemia, and the red cells showed no abnormalities. The platelet count was 240,000, the reticulocytes numbered 0.8 per cent. The coagulation time was 8 minutes, the bleeding time $1\frac{1}{2}$ minutes. The patient's blood group is "A" (international nomenclature). The sedimentation rate was not determined

Investigation of the relatives of the patient was disappointing. He has had no children, and both his brothers are dead. Examination of smears of all the children and grandchildren of these brothers, to the number of eight, and of two cousins, failed to reveal the anomaly in any of them. It is therefore impossible to state positively whether the condition in this person is familial or not, but since all of the cases reported in the literature have been familial, it may be assumed that it is

The family history reveals a tendency to arterial disease. One brother died at 50 of a ruptured aneurysm of the iliac artery, the result of atheroma, the other died suddenly, of coronary occlusion, at the age of 57. The only sister was still-born. The father, however, lived to the age of 96

Physical examination, April 22, 1937. Age 73 years. A tall thin man weighing 148 pounds. Color fair, pupils equal and react to light, arcus senilis present, sclerae faintly yellowish. Mouth and throat negative. Thyroid gland and lymph nodes not enlarged. Heart of normal size, action regular, there is a rather loud systolic murmur in the aortic area, transmitted towards the neck. Pulse rate 56, blood pressure 104 systolic and 58 diastolic, the peripheral arteries are moderately thickened. Abdomen natural, liver and spleen not enlarged. Knee jerks and plantar reflexes normal. On the skin of the neck and upper part of the chest anteriorly there are numerous rounded or flattened papules of a yellowish-white color, a biopsy was done, and a diagnosis of multiple benign cystic epithelioma was made. The urine is negative. Wassermann and Kahn tests of the blood negative. Blood group "A" (international nomenclature). The patient has shown a pronounced arcus senilis and a systolic murmur in the aortic area since the age of 47 years

DISCUSSION OF THE LITERATURE

The blood picture as first discovered by Pelger has been verified by all subsequent observers. Unfortunately Pelger's description is not to be found in print, except as quoted by some of the Dutch writers, for the account of his original communication to the Dutch Pathological Society⁶ merely alludes to a demonstration of two patients with a rare anomaly of the

leukocytes, without any description of the blood picture, the promised extensive article on the subject never appeared. Staff cells have been present in large numbers in all cases, and have almost invariably exceeded the segmented forms. Cells with more than two nuclei have been found rarely, or not at all. The shift to the left has gone as far as juvenile cells, but myelocytes very seldom have been noted, and then in small numbers (0.5 per cent, Schilling). The proportion of juvenile cells has varied widely, as might be expected on taking into account the element of subjectivity in the classification of this form of cell. Schilling, on examining smears from 11 cases, found the juveniles making up the majority of the non-segmented cells, but Undritz recorded only from 2 to 9 per cent.

All authors are agreed that the eosinophiles are involved in the shift, but as regards the basophiles opinions are divided. No extensive studies of the basophiles have been made.

Toxic granulation of the protoplasm of the neutrophils has been absent, except in one of Zundel's cases.

The response to infection has been reported only in one instance, in one of Huet's cases during an acute unspecified infection the percentage of staff cells rose from 26 to 44 per cent.

No studies of the bone marrow have been made, nor have any autopsies been performed.

The sedimentation rate has been normal in all the cases in which it has been measured, in contrast to the increased rate met with in the infectious shift to the left.

Blood grouping seldom has been determined, Jordan's patient belonged to group "O," the writer's to group "A."

The familial character of the anomaly has been proved in all the cases reported up to the present time, with the exception of Pelger's second patient, and the case of Chevallier and Ély,³ in both of which the relatives were not investigated. The trait has been found present in three generations by Huet, Jordans⁺ and Peterson. It has been transmitted by both sexes, and males and females are affected in equal proportions (exactly 50 per cent of each). It is therefore not sex-linked. In no case have the offspring of unaffected members shown the anomaly. The proportion of the affected among the children of affected parents has varied from 50 to 100 per cent, Aheff and Reekers found 7 out of 14 affected, Huet 3 out of 6, Jordans 6 of 9 in the second generation, 3 of 6 in the third, Zundel 4 of 6, and 3 of 4 in the second and third generations respectively. The highest incidence was in the family of Undritz, in which all of 5 living members of the second generation were affected (two had died without investigation), and all of 3 siblings in the third generation. In no instance have both husband and wife been proved to be bearers of the trait.

* Jordans' family is identical with family "Q" of Burger, the family tree is completed in Burger's article.

It is thus apparent that the anomaly is a dominant Mendelian character, not sex-linked

A large majority of the affected persons have been healthy, and there is no evidence that there is any unusual tendency to disease in these families. Many of them have had members who were tuberculous, but this may be accounted for by the ubiquity of this malady, and by the fact that the anomaly is more likely to be detected in the case of tuberculous patients in sanatoria, because of the periodical examinations of the blood which are made there. The Wassermann test has been negative in all of the cases in which it has been done. The association with hyperthyroidism in Peterson's family (5 cases) is unique in the literature.

The occurrence of this anomaly exclusively as an inherited trait indicates that the segmentation of the nuclei of the neutrophils and eosinophils is regulated by a constitutional factor. When this becomes modified by the process of mutation, the anomaly takes place, and is transmitted to the descendants as a dominant character.

Diagnosis The diagnosis can be made from the stained smear by one who is familiar with the condition, on the following points: (1) The even contour and tendency to kidney shape with rounded ends on the part of the nuclei of the staff cells, (2) the failure to find neutrophils with more than two nuclei, and (3) the absence of toxic granulation. In all of these respects the blood picture differs from the infectious shift to the left. In case of doubt the absence of signs of infection in the patient, and investigation of the relatives will clarify the situation. Failure to recognize the condition may lead to a serious mistake in prognosis.

The anomaly might be of medico-legal importance, as regards questions of identity and paternity.

Prognosis From the evidence available, it appears that the health of persons with this anomaly is not adversely affected, and that their leukocytes are adequate so far as function is concerned.

SUMMARY AND CONCLUSIONS

1 A case of familial shift to the left of the leukocytes is reported, in which no other members of the family were found to be affected, probably on account of the lack of direct descendants.

2 The typical blood picture was present, viz., a high percentage of staff cells, mostly of crescentic or kidney shape, absence or extreme rarity of segmented forms with more than two nuclei, even contour of the nuclei, and absence of toxic granulation.

3 The literature is discussed.

The writer extends his thanks to Dr. R. M. Thomas and Prof. George H. Smith for assistance in the blood studies, and to Professor J. G. Dussier de Barenne for translating the Dutch articles.

CASE REPORTS

TRANSVERSE MYELITIS FOLLOWING MUMPS^{*}

By A C FORTNEY, M D , *Fargo, North Dakota*

ALTHOUGH it is not unusual to find meningitis, encephalitis, neuritis, and delirium as complications of mumps, myelitis is most uncommon. Woltman and McKaig reported such a case in 1933, and at that time a very close search of the literature revealed only one other case, that of Warrington's reported in 1914. However, a third case was reported by Kuligowski in October 1933. I should like to add another to those reported.

CASE REPORT

Mr N E, white male, aged 39, hardware dealer, first contracted mumps on December 26, 1935. Involvement first appeared in the right parotid, and four days later the left side became swollen. Mild bilateral orchitis developed, but rapidly subsided. His symptoms were mild. Delirium, headache, and neuritis did not appear. He did not feel sick enough to remain in bed longer than two days. On the evening of January 6, 1936, twelve days after the onset of the mumps he first noticed a little tingling in the soles of both feet. He had had no headache nor any pain in the neck or back. By the afternoon of January 8 his legs were so weak that he had to hang onto chairs or the wall to keep from falling down. By this time the tingling in the soles of the feet and legs had given away to a numb feeling. At this time, it had been 16 hours since he had urinated, and 24 hours since his bowels had moved. In spite of this he had neither the desire to urinate or defecate, nor did he experience any pain in the region of the bladder. Large doses of patent cathartics failed to move his bowels.

The next morning, January 9, his family physician was called who catheterized him, and obtained a large amount of urine which was not measured. A large soapy enema was given but had to be siphoned off as the patient was unable to expel it. His temperature was 100° F, pulse 84 and white blood cells 10,500. The patient was then moved to a hospital, where I saw him in consultation with Dr O S Crause of Towner, North Dakota, on January 10. A spinal puncture on admission revealed clear fluid under normal pressure. Five cells were counted and there was a trace of globulin.

Past History He had never had mumps until the present attack. He had had the other usual childhood diseases without any complications. He had had no serious illnesses, injuries, or operations.

Family History Father died of arteriosclerosis. Mother living and well. Three brothers are living and well. No history of cancer, tuberculosis, diabetes, or insanity.

Physical Examination The patient was a well developed and nourished white male of apparent age lying quietly in bed in no distress. The respirations are free and easy, cyanosis is absent and orientation is normal. The entire physical examination except as related to the nervous system is negative.

* Received for publication February 26, 1937.

From the Department of Internal Medicine, Hanna, Clay and Lancaster Clinic, Fargo, N. Dak.

Neurological Examination The pupils are equal and regular and respond normally to light and accommodation. The fundi are normal. Extra ocular movements are normal. The patient has noticed no diplopia. The ears are normal, and hearing as tested with a watch is normal for both ears. There is no demonstrable weakness of the facial muscles. Sensation to pin prick, cotton, heat and cold over the face, neck, and scalp is intact. The tongue protrudes in a straight line and the gag reflex is present. There is no difficulty in swallowing water or solid foods. There is no weakness of the sternocleidomastoid muscles. There is slight rigidity of the muscles of the neck to anterior flexion. There is no swelling of the parotid glands.

Sensation, motor power, and reflexes are normal in the upper right extremity. There is a slight but definite weakness of the entire upper left extremity to all movements. The biceps and triceps reflexes are hyperactive. Sensation to pain, light, touch and temperature changes is slightly impaired in this member.

At the level of the third rib, diminution of sensation to pain, light touch and temperature begins to appear. From the level of the fifth rib and downward, these sensations are completely lost. The abdominal and cremasteric reflexes are absent. On auscultation of the abdomen, peristalsis is noted, and seems to be of normal intensity.

Both lower extremities are completely flaccid, and all superficial sensation is lost. Deep sensation is present. The patellar and ankle reflexes are weak. Patellar and ankle clonus is absent. There is bilateral positive Babinski and Oppenheim. On the right, position sense for the toes is normal, but erratic on the left. There is complete loss of bladder control. The rectal sphincter is toneless and the rectum remains widely opened after digital examination.

A spinal puncture was performed without anesthesia, the patient being aware only of a pressing feeling in the back. The fluid was clear and under 10 mm of mercury pressure. On jugular compression the pressure promptly rose to 24 mm and when released, promptly fell to its original level. Fifteen cc of the fluid were removed and the neck rigidity which was previously noted completely disappeared.

A diagnosis of transverse myelitis, probably due to the virus of epidemic parotitis, was made. It was felt that the outcome depended entirely upon the degree of permanent damage to the cord which only time would tell. It was further felt that cystitis and possibly pyelitis would result from the frequent catheterizations, and that this factor would be the most important in determining whether or not the patient would survive. Absolute bed rest, abstinence from any passive manipulations until improvement began, and splinting of flaccid extremities were ordered. Rigid attention to the care of the skin was emphasized. No medication was ordered except that necessary for intermittent alkalinization and acidification of the urine.

Progress In the next few days the left arm became practically useless and flaccid. Following this there was very little change in the patient's condition up to the time he was discharged from the Hospital, on February 13, 1936. The only sign of return of function at that time was the ability to move the great toe on the right foot. The hospital regime was continued at home and gradual improvement began.

I next saw him on May 3, 1936. At the time he was in the best of spirits, and thoroughly convinced that he was going to get well. Power in the left upper extremity was now comparable to that of the right. He was able to come to a sitting position in bed without any assistance. The abdominal reflexes and cremasteric reflexes were sluggish. A rounded, rather tense, painful mass appeared above the symphysis to a point half way to the umbilicus. This was a distended bladder. The patient was able to move in any direction in bed without aid. However, on determining the strength passively in his legs it was still found to be much diminished, in the left more so than in the right. Astereognosis and adiadokokinesis were absent. Position sense of the toes was normal. Sensation to pin pricks, cotton, and tem-

perature changes was practically normal over the entire body. A specimen of urine was bloody. Patient was having a definite overflow type of urination, and was still being catheterized daily. It was evident that a severe cystitis was present. The temperature showed daily fluctuations, going as high as 100.5° F.

The remainder of the physical examination was normal. At that time it was evident that the patient was making very satisfactory progress in every way except in regard to the urinary tract infection. The risk of a general infection was still a definite one. In July 1936, he returned to the Hospital and a cystotomy with supra pubic drainage was done. Since then his urinary infection has cleared up considerably and now he has complete control of the bladder and bowels. He is able to walk around with practically no difficulty. The patient may be classified as a completely recovered case.

SUMMARY

A case of myelitis following mumps is presented. The rarity of the entity is made note of, there being only three other cases reported in the available literature. This case corresponds very closely as to time of onset, symptoms and clinical findings to those reported by Woltman, Warrington and Kuligowski except for the absence of back pains.

The prognosis in this type of complications must be guarded. In the four cases reported, one died on the ninth day of illness, one showed no improvement 19 months after onset, one was completely well at the end of eight weeks, and the case reported here showed complete recovery at the end of seven months. Only conservative treatment was instituted. However, the use of convalescent serum intra-spinaly and intra-venously and the employment of frequent spinal puncture might well be given a trial in such instances of spinal cord involvement following mumps.

INTERNAL HYDROCEPHALUS FOLLOWING REPEATED INTRAVENTRICULAR HEMORRHAGES *

By FRANCIS J. SCULLY, M.D., F.A.C.P., *Hot Springs, Arkansas*

SPONTANEOUS intraventricular hemorrhage is quite rare and when it occurs is usually promptly fatal. A recurrence of such a hemorrhage is therefore quite unusual. The following case is especially interesting because of the development of an extensive internal hydrocephalus following repeated intraventricular hemorrhages.

CASE REPORT

Mrs. J. S., aged 60, was seen in consultation with Dr. H. A. Ross of Arkadelphia on November 1, on account of a persistent headache and dizziness. On October 16

* Received for publication August 24, 1936

the patient had suddenly dropped over unconscious while sewing. She had previously felt well, and that morning had eaten breakfast as usual. She remained comatose for about 15 minutes. Following this attack she had developed headache, which gradually became more severe and had continued since. She required morphine, bromides, and amytal to keep her comfortable. The headache was persistent and extended down into the back of the neck. For three days there was rather marked vomiting and the vision became blurred. These symptoms had shown improvement until on October 31, when she had two mild convulsive attacks with some movement of the right arm over the chest. At the onset of the illness the blood pressure was 180 mm of Hg systolic.

The patient had had influenza five years before. A panhysterectomy had been performed 20 years before on account of a tumor of the uterus, which was thought to be cancerous. She had borne six children, five of whom are living.

Examination showed the patient to be rather pale and in a semi-stupor. The heart and lungs were normal. Blood pressure 160 systolic and 80 diastolic, pulse 60, temperature 98.4° F. The peripheral vessels showed a moderate sclerosis. The pupils were small and equal, and reacted only slightly to direct light due to opiates. Ophthalmoscopic examination showed a choking of both discs. The tongue was extruded in the midline. The deep reflexes were active and there was no paralysis or sensory changes in the extremities.

Laboratory tests showed hemoglobin 60 per cent, red blood cells 3,280,000, and white blood cells 10,100. The Wassermann test was negative on both the blood and the spinal fluid. The spinal puncture yielded fluid under increased pressure, showing a heavy trace of globulin and many red blood cells. The fluid was of a golden yellow color, but did not clot on standing.

From these findings it was thought the patient had a brain tumor in which a hemorrhage had occurred, and that the convulsive attacks had appeared during the period of active bleeding. Since there were no localizing symptoms, and since there had been a period of recovery after the first hemorrhage, it was thought best to keep her quiet in bed and to use sufficient sedatives to control the discomfort, in the hope that the bleeding would subside and that immediate surgical intervention would not be required.

During the month of November the patient improved. There were several mild attacks but no stupor following them. There was improvement in the vision and when seen by Dr. O. H. King, on November 20, the eye grounds were normal.

On December 2 the patient had a severe convulsive attack, with gradually increasing stupor, which continued until she died.

Autopsy. The brain was removed and examined by Dr. D. C. Lee, who reported that on section the brain showed a marked internal hydrocephalus. The lateral ventricles were markedly dilated and the septum between them was obliterated. The third and fourth ventricles were also dilated. All the ventricles were filled with clotted blood. There was some blood extending out from the fourth ventricle on the base of the cerebellum. The corpus callosum was very much thinned and the dilated ventricles measured 10 by 5 cm. at the base of the anterior horn. In the anterior horn of the right lateral ventricle there was a spongy mass about 4 cm. long and 2 cm. wide. It was attached loosely to the inner and lower wall of the ventricle at the anterior portion of the choroid plexus. No tumor mass could be found. On microscopic examination the mass proved to be an organized blood clot, with a number of dilated vessels of the choroid plexus included.

DISCUSSION

From the pathological findings it was evident that this patient had had repeated hemorrhages from the anterior portion of the choroid plexus in the right

lateral ventricle and that the bleeding had been sufficient each time to fill the ventricles with blood causing an internal hydrocephalus. The blood pressure was above normal which made the hemorrhage more likely to occur. The convulsive attacks occurred with each repeated hemorrhage. When the spinal puncture was made in November the golden yellow color was due to the previous hemorrhage, and the red cells found were probably due to the hemorrhage that had occurred the day before. With each hemorrhage there would be sufficient pressure on the brain to produce the convulsion, and to cause the interference with vision which was noted. With the absorption of the blood these symptoms would subside. The organized clot of blood was a further indication of the repeated hemorrhage and of the attempt of the body to control the bleeding. The last hemorrhage was so marked that the vital centers of the brain were too depressed for the individual to survive.

Intraventricular hemorrhage is not uncommon in severe traumatic injuries to the head and brain. In newborn infants it also occurs more often than is generally suspected. Hemsath¹ reports its occurrence in 4.8 per cent of a series of 414 autopsies of still born and newborn infants. Occasionally in massive cerebral hemorrhages the bleeding will extend from the internal capsule into the ventricle.

Spontaneous intraventricular hemorrhage having its origin in the ventricle is quite rare. Copeland² reports one case in a man, aged 51, with arteriosclerosis and hypertension. The hemorrhage had its origin in the walls of the aqueduct. Sands and Lederer³ reported three cases, two with arteriosclerosis, and one with intracranial aneurysm. They state that the diagnosis of intraventricular hemorrhage is very difficult even under the most ideal conditions. A good review of the symptoms in these cases is given in their article.

Apparently intraventricular tumors do not give rise to hemorrhage as often as one would suppose. Dandy,⁴ in 1933, reported 13 cases of benign tumors in the ventricle, and reviewed 25 additional cases from the literature. In one of his cases a venous aneurysm in the wall of the ventricle was removed after a second hemorrhage had occurred in the right ventricle. Eight additional cases were reported in 1934 by Fincher,⁵ but none of them were accompanied by hemorrhage.

In the case reported above it was not possible to determine whether there was an aneurysm of the vessels of the choroid plexus at the point where the hemorrhage occurred. On microscopic section it was noted that the vessels were very thin and dilated where they were a part of the organized clot of blood. It is possible that these thin vessels had ruptured with some sudden increase of the blood pressure, which was already high, and that the clot which formed was not sufficient to prevent subsequent bleeding.

EDITORIAL

CERTAIN TOXIC EFFECTS OF SULFANILAMIDE

Many men in the past months have likened in their minds the present era in the treatment of infections to that period of excitement which immediately followed the first clinical use of Ehrlich's "606". Indeed many have felt that in the new drug, sulfanilamide, the medical profession had obtained a therapeutic agent of greater importance to humanity than even salvarsan itself.

So chastened are many medical men as a result of repeated chemo-therapeutic disappointments that the earlier announcements of the striking influence of this drug on certain coccal infections were met with a certain degree of cynicism. A larger number, however, not only readily accepted the value of the drug in streptococcal infections but, forgetful of the bitter lessons of cinchophen, amidopyrine, and dinitrophenol, promptly hastened to try the drug in every conceivable condition without heed of possible danger. The therapeutic reports already at hand must convince the most skeptical of the undoubted value of this potent new remedy. It is almost breath-taking to read of the results obtained in such highly fatal conditions as streptococcus meningitis, streptococcus septicemia, puerperal fever and in meningococcus meningitis. On the other hand there is no doubt that the drug exhibits toxic effects and that in some cases these may be of a serious nature. There is a wealth of recent reports on these toxic manifestations. It is important, therefore, for every man in the practice of medicine to be able to weigh carefully the relative advantages and disadvantages of the employment of this drug.

Whatever is written concerning the subject of sulfanilamide today may well be out-dated or contradicted by the contents of next month's medical journals, but at the moment it would seem that while there is a highly varied set of toxic manifestations which may follow the use of this chemo-therapeutic agent, yet on the whole we have reason to think that for the most part they are minor in nature and that even those of a more threatening type can apparently be successfully combated. It must be borne in mind, however, that for the most part reports have dealt with the immediately acute effects of the drug resulting from short courses of its administration. Whether, later, more serious injuries may be reported as a result of its prolonged use, or whether delayed reactions may become manifest at a later period in those who have apparently utilized it without harm, remains to be seen.

A great deal of interest is attached to those toxic effects involving the skin. Not far from one in twenty of the patients receiving this drug develop a rash. The most usual form of eruption resembles measles rather closely, there may be mild constitutional symptoms, fever and malaise,

accompanying its appearance. The rash is most apt to occur after the drug has been taken for five days or more. It disappears fairly promptly upon discontinuance of the sulfanilamide but may recur if more of the drug is taken. Recently an interesting observation has been made by several authors^{1, 2, 3} that a more violent form of eruption may occur in those who have been taking this drug, over such areas of the body as are exposed to sunlight. In certain of these cases there has been a marked swelling of the affected part, edema and infiltration of the skin, and large coalescent macules and papules of a pink to dusky red color. The skin condition may progress to a marked vesiculation. In convalescence it is followed by desquamation. With the onset of this severe eruption, there may be quite marked nausea, chills and fever. The nature of the photosensitivity in these cases has not been further investigated.

Cyanosis is very common in those taking the drug and its intensity is often quite alarming. There is still a great deal of confusion as to the nature of this abnormal coloration. Some have attributed it to the presence of methemoglobin, others to sulphemoglobin, but equally careful observers have been unable to find evidence of either of these forms of hemoglobin and they are inclined to believe that in certain instances, at least, there is a new abnormal compound formed in the blood which gives it its cyanotic color. The cyanosis is not accompanied by any evidence of distress on the patient's part and when because of the seriousness of the infection, the drug has been continued regardless of the patient's color no apparently harmful consequences have followed.

It has been discovered⁴ that slight degrees of acidosis, as determined by a lowering of the CO₂ combining power of the blood, are present in a considerable proportion of patients taking sulfanilamide. Since in a few cases the degree of acidosis has been quite severe, it has been recommended that 10 grains of sodium bicarbonate be given with each dose of sulfanilamide.

Among the most striking and serious of the toxic effects which have been so far observed are those involving disturbance of the normal blood picture. Slight grades of anemia have been frequently noted, apparently as a consequence of full doses of the drug. Quite different, however, are the cases of acute hemolytic anemia^{5, 6} which may come on very suddenly in patients taking routine dosages of this new remedy. Pallor, profound weakness, and

jaundice accompany the rapid fall in the red count. If the process is severe, the blood serum may be port wine color from the liberated hemoglobin and the urine a dark brown from hemoglobinuria. In a case recently seen the red count fell from 4.5 million to 700,000 in less than two days. Fortunately, cessation of the drug is apparently followed at once by cessation of the hemolytic process. Transfusions are very helpful in tiding the patient over the acute phase of the process. Cases observed so far have all recovered.

There has been a great deal of fear from the start that the drug might cause granulocytopenia. There have been a few undoubted cases and in one at least of these death was attributed to this complication of treatment. However, in most of the relatively few cases so far reported recovery has been prompt upon removal of the drug.

Patients taking the drug very usually notice some slight general symptoms of the nature of dizziness, slight headache and ringing in the ears. These may safely be ignored. More serious neurological effects such as have been described in experimental animals have not appeared in man. An exception to this rule is the case of a patient recently reported⁷ who developed a toxic optic neuritis with severe temporary loss of vision. Fortunately, the recovery of this patient is apparently going to be complete.

It is well, of course, for the physician who contemplates using this drug to be aware of the nature of the toxic effects which may be produced. In certain instances these effects seem to be dependent to some extent upon the size of the dosage and the length of time it had been employed. There is some evidence that this is particularly true of the skin eruptions. On the other hand, the acute hemolytic anemia and the granulocytopenia appear to be due to idiosyncrasy. They may appear on normal dosage within the first few days after the drug has been started. It is not likely then that the occurrence of a certain percentage of these cases can be avoided.

It is believed that the use of sulfates, such as magnesium sulfate and ferrous sulfate simultaneously taken with sulfanilamide, predisposes to the formation of sulphemoglobin and perhaps to other complications. It has been suggested that paraldehyd diminishes the efficacy of the drug. A safe rule would be to avoid concurrent therapy with other medicinal preparations if this is feasible. The physician should recall too that sulfanilamide is excreted almost entirely through the kidney. When the renal apparatus is normal excretion of the drug is fairly rapid, and it is this rapid excretion, no doubt, which tends to cut short the toxic manifestations as soon as the intake of the drug is discontinued. On this account, however, the giving of the drug to a patient with chronic or acute nephritis carries with it a hazard that if toxic effects occur, they will perhaps be more prolonged and more serious than in the patient with normal excretory powers. It is certainly the part of caution also, that during the course of administration of

⁷ Bucy, P. C. Toxic optic neuritis resulting from sulfanilamide, Jr. Am. Med. Assoc. 1937, civ, 1007.

the drug, the patient should be kept at rest and under daily observation. It would be a wise rule also to warn all patients not to expose themselves to strong direct sunlight.

As in the case of all new remedies the physician is called upon to balance carefully in his mind the importance of the advantage to be gained by the use of the drug against the possible disadvantages of its as yet only partially known toxic effects. The conservative physician will not use this powerful remedy unless he is faced with a disease of dangerous character not equally amenable to other forms of treatment.

REVIEWS

To Drink or Not to Drink By CHARLES H. DURTEE Longmans, Green and Co., New York 1937 Price, \$1.00

This interesting and lucid book on the problem drinker deals with but one aspect of the chronic alcoholic problem. The author does not undertake to discuss those diverse pathological mental problems associated with or proximal to chronic alcoholism.
